ALL who follow the medical profession must be students for ever—students as much in the fifth year of their curriculum as in the first; students as much at the end of their life's work as when confronted with their earliest patients. From every case for the real physician and the genuine surgeon a lesson has to be drawn: perhaps a new point arises, perhaps only a point confirmatory of what has been previously familiar; but in either instance something worth knowing has to be learned. And this is at once the great difference between book-learning and the learning that is the outcome of practical observation. To a certain extent the need for book-learning may be finite, and to a great extent this need is modified by the idiosyncrasy of the individual. But no man from the moment that he places his foot on the lowest rung of the ladder of medicine can dispense with observation or the results of observation. This need is never finite. A certain quickness in the detection of, and a certain facility in the reading of, the meaning of symptoms and signs and the influence of family history and environment are given to some in an extraordinary degree; but most certainly, should any man, being gifted in this fortunate manner, presume to think lightly of, perhaps to forego, some of the routine of observation, in the end he will be the worse off for his talents. He will make errors, and will speedily know himself, and others will as speedily know him, to be a superficial and unreliable, albeit occasionally brilliant, adviser. For book-learning there is a substitute—practical work; for practical work there is no substitute.

And this difference between book-learning and the learning that is the outcome of practical work and of the use of all opportunities for observation precisely defines the right method of using books. They are to be employed in whatever way will best assist in practical work. They are means to this end only. But all cannot employ books in the same way. Their use must vary immensely with the bent of the student's mind and the habits of work which he finds most readily conduce to the sure and speedy acquisition of knowledge. So that in the selection of a text-book, always a matter of great importance to the student, not only the large number and variety of works render the choice exceedingly difficult, but infallible advice cannot be given; for good council to one man will be less valuable to another. In the appended lists of the standard text-books we have endeavoured by brief general remarks to divide the books more or less into three classes—two comprising books specially designed to assist the student in his examinations, being elementary or comprehensive works required respectively for pass or honour examinations; while the third class includes books of reference not designed to be exhaustively read by anybody, but rather to be consulted as a second or elucidatory opinion where anything in the text-books proper seems obscure or incomplete. But the use that the student will be able to make of these three classes of books will vary entirely with his order of mind. To one man the small elementary book may be well-nigh sufficient reading. He will be able to use it as the skeleton of his knowledge and will endow it with tissues and life from his personal observation, by practical courses in his school, by clinical work in the wards, and by thoughtful attendance at lectures. This is the student into whose work books do not largely enter. But inasmuch as it is easy to examine fairly and thoroughly upon book work, while it is difficult to lay down proper standards, and discover adequate tests, for the appraisement of practical work, the result of examinations must more or less depend upon the ability of the student to answer somewhat in text-book language questions framed somewhat upon text-book lines. Therefore it will be well for the student whose practical order of mind enables him, as it were, to write his own text-book by grafting his practical work on to an elementary manual, to revise his knowledge before entering for an examination by the light of a first-class text-book. This is the best and most feasible way of combining books and practical and clinical work for the formation of a medical education. But it is not in the power of every student to obtain an education in this manner. Practical work is easier to some men than to others, and lectures mean more to some men than to others. The receptive man will benefit by teaching which only arouses opposition in the critical man. The reading of a large text-book by the critically-minded man—the man whose first impulse on hearing a fact is to doubt it or the deductions from it—may very often be the best way in which such a man can gain a knowledge of his subject. He gets an all-round look at it, and though he may not entirely understand everything that he reads he will obtain a general familiarity with this topic, and see the fallacy of the objections which rise in his mind. The bald statements for which alone the small manual can find room would arouse in him nothing but opposition, and he will be well advised to go straight to the big book where the explanations are included with the facts. But he *must* supplement his wider range of reading with as honest and as earnest a course of practical work as his less literary fellow-students. When confronted with his examination he will find, as hundreds of the most promising students of medicine have found to their considerable discomfiture, that practical work is absolutely necessary, that without it book-work is as nothing, that even to pass in the written part of the examination (for which he feels so amply equipped) will be almost impossible unless his knowledge is fortified and made alive by some measure of practical experience, and, lastly, that no amount of book-work will ever enable him to answer questions by word of mouth.

The short notes upon well-known text-books which follow will enable the student to ascertain the scope of each work, and, with the assistance of advice from his lecturer, he will be able to decide which book is most likely to suit him—that is, which book will best enable him to obtain full benefit from his practical work. He will not be able, perhaps, to decide this point at once; if he is just beginning his career he cannot know for certain in which direction difficulties will assail him. But those are the points we desire to make for his information and encouragement: firstly, all good sound text-books have their place, for knowledge presented in one form to one man is more easily digested if presented in another form to another man; and secondly, he must not be disheartened if books (or a particular book) seem to mean more to a fellow-student than they do to him. It is natural that this should be so. If one student finds it difficult to follow the arguments of the larger treatises it is more than possible that to him all sorts of practical work will come as an illuminant. If another man finds that practical work wearies him and puzzles him, although he is earnestly, honestly, and conscientiously desirous of going through his proper course and learning all that it should teach him, it is quite possible that what he requires is a general grasp of his subject, a sort of broad outline of it which would give a meaning to the details that he finds it so wearisome to acquire. It is unnecessary to say that our list of books might be considerably extended. It would be so if we had designed to make it exhaustive. But we do not suggest that the books which we mention are the only ones which the student can read with advantage. His regular course of reading will be dictated properly by advice from the lecturers at his school, and, in a measure, by the prevalent fashion at that school. We have only intended to place before him succinct information that shall guide him in his choice, while pointing out to him that all educational books are but a means to an end, and that end is practical knowledge.

ANATOMY.

The standard text-books on Systematic Anatomy are Quain's and Gray's. Both of these have been recently brought up to date. Quain's is the more scientific work, and is, indeed, the most advanced and comprehensive treatise on the subject in the English language, if not in all languages. Its morphological, histological, and visceral anatomy is unequalled. The volume on Embryology by Professor E. A. Schäfer is the clearest and best history of development with which we are acquainted. An appendix has been published on Superficial and Surface Anatomy by Professor Thane and Professor Godlee. The work is now published in separate parts.

Quain's (*Jones*) *Elements of Anatomy*. Longmans, Green, and Co. The tenth edition. Edited by EDWARD ALBERT SCHÄFER, F.R.S., Professor of Physiology and Histology in University College, London; and GEORGE DANCER THANE, Professor of Anatomy in University College, London. In three volumes. Vol. I., Part I. Embryology. By Professor Schäfer. Illustrated by 200 Engravings, many of which are coloured. 9*s*. Vol. I., Part II. General Anatomy or Histology. By

Digitized by Google

Professor Schäfer. Illustrated by nearly 500 Engravings, many of which are coloured. 12*s.* 6*d.* Vol. II., Part I. Osteology. By Professor Thane. Illustrated by 168 Engravings. 9*s.* Vol. II., Part II. Arthrology, Myology, Angeiology. By Professor Thane. Illustrated by 255 Engravings, many of which are coloured. 18*s.* Vol. III., Part I. Spinal Cord and Brain By Professor Schäfer. Illustrated by 139 Engravings. 12*s.* 6*d.* Vol. III., Part II. The Nerves. By Professor Thane. Illustrated with 102 Engravings, many of which are coloured. 9*s.* Vol. III., Part III. Organs of the Senses. By Professor Schäfer. Illustrated by 178 Engravings. 9*s.* Vol. III., Part IV. Splanchnology. By E. A. Schäfer, F.R.S., and Johnson Symington, M.D. With 337 Illustrations. 16*s.* Appendix. Superficial and Surgical Anatomy. By Professor G. D. Thane and Professor R. J. Godlee. With 29 Illustrations. 6*s.* 6*d.*

Anatomy, Descriptive and Surgical. By HENRY GRAY, F.R.S., late Lecturer on Anatomy at St. George's Hospital. The thirteenth edition. 36*s.* London: Longmans, Green, and Co. Re-edited by T. PICKERING PICK, Surgeon to St. George's Hospital, Member of the Court of Examiners, Royal College of Surgeons of England. There are 636 large Woodcut Illustrations, a large proportion of which are coloured, the arteries being coloured red, the veins blue, and the nerves yellow. The attachments of the muscles to the bones in the section on Osteology are also shown in coloured outline.—*Gray's Anatomy* occupies a place only second to Quain's. In popularity it is doubtful if it does not actually precede its larger rival, and for mere everyday work it has points of superiority; in many instances the diagrams are much clearer, if somewhat more diagrammatic, excessive detail being omitted.

Human Anatomy: a Treatise by various Authors. Edited by HENRY MORRIS, M.A., M B. Lond., F.R.C.S., Surgeon to, and Lecturer on Surgery at, the Middlesex Hospital, with 791 Illustrations, nearly all original, and many of them in several colours. 40*s.*—This is an excellent work. We may mention especially the description of the peritoneum, in which the arrangement of that complicated structure is set out with admirable clearness. (In one volume or in three parts.) 1893. London: J. & A. Churchill.

A Manual of Anatomy for Senior Students. By EDMUND OWEN, M.B., F.R.C.S., Senior Surgeon to the Hospital for Sick Children, Great Ormond-street, Surgeon to St. Mary's Hospital, London, and co-Lecturer on Surgery, late Lecturer on Anatomy, in its Medical School. With 210 Illustrations. Price 12*s.* 6*d.* Longmans, Green, and Co.

A Text-book of Human Anatomy: Systematic and Topographical. By ALEXANDER MACALISTER, M.A., M.D., F.R.S., F.S.A., Professor of Anatomy in the University of Cambridge, and Fellow of St. John's College, Examiner in Human Anatomy, University of London. Includes the Embryology, Histology, and Morphology of Man, with special reference to the requirements of Practical Surgery and Medicine. One vol. 1889. 816 Illustrations. 36*s.* London: Charles Griffin and Co.—It is in many respects the most important work on the subject that has appeared in recent years, being thoroughly comprehensive, lucid, and up to date. It is especially suited for senior students.

Wilson's Anatomist's Vade-Mecum. Eleventh edition. By HENRY E. CLARK, M.R.C.S. Eng., F.F.P.S. Glasg., Examiner in Anatomy, F.P.S., and Professor of Surgery in St Mungo's College, Glasgow. With 492 Engravings and 26 Coloured Plates. 18*s.* 1892. London: J. & A. Churchill.

The Anatomy of the Joints of Man. By HENRY MORRIS, F.R.C.S. 1879. 8vo. 16*s.* J. & A. Churchill.—This is perhaps the most complete book on the subject yet published. The work is fully illustrated, and many of the illustrations are in colour. Besides the bones, ligaments, and synovial membranes, the various features connected with the arterial and nervous supply of the joints, the bursæ, and the muscles which act upon the joints are very thoroughly dealt with

In Practical Anatomy the student has the choice of text-books by Ellis, Cunningham, Heath, and Cleland. The favourite dissecting-room manuals are probably those of Ellis and Cunningham.

Ellis's Demonstrations of Anatomy, as edited by Professor THANE, have been studied by generations of dissectors, and for accuracy and thoroughness leave nothing to be desired.—*Cunningham's Practical Anatomy* is a very clear, well-written book, and fully illustrated. It has the advantage of being published in separate volumes. It is steadily growing in favour and has many points of superiority.—*Heath's Practical Anatomy* is a smaller work, clearly written, and forming a compendious introduction to the subject.—*Professor Cleland's Directory for Dissection* is purely a guide, and as it is small and cheap and contains full practical directions to the dissector it will be found most useful in the dissecting-room.

Demonstrations of Anatomy. By GEORGE VINER ELLIS, F.R.C.S. Eleventh edition. 1890. Pp. 782. 12*s.* 6*d.* London: Smith, Elder, and Co.

Cunningham's Manual of Practical Anatomy. Second edition. In two vols., cloth, illustrated with 372 Wood Engravings and two Coloured Plates. Vol. I.: Upper Limb, Lower Limb, Abdomen; Vol. II.: Thorax, Head, and Neck. Price, 12*s.* 6*d.* each volume. Young J. Pentland, Edinburgh.

Heath's Practical Anatomy. Edited by W. ANDERSON, F.R.C.S. With 329 Engravings. 1893. Pp. 744. 15*s.* London: J. & A. Churchill.

Directory for Dissection By Professor CLELAND, M.D. Ed. Third edition. 1888. Pp. 191. 3*s.* 6*d.* London: Smith, Elder, and Co.

Dissections Illustrated. By C. GORDON BRODIE, F.R.C.S. A graphic handbook for students of anatomy; 73 Coloured Plates and 37 Diagrams. 42*s.* London and New York: Whittaker and Co. It is also published in four parts.—This is an admirable book and should find a place in every student's library.

Applied Anatomy may be studied from the works of Treves, Bellamy, Holden, or Maclachlan.

Holden's Landmarks, Medical and Surgical, like all his work, is distinguished by its clearness of arrangement and correctness of detail. The English is perfect and the illustrations excellent. It thoroughly justifies its popularity in every way.—*Treves's Surgical Applied Anatomy* and the *Guide to Surgical Anatomy* by EDW. BELLAMY are both in general use in our schools. The former is particularly full of information, conveyed in such a way that it is likely to "stick" in the student's memory.—*Malachlan's Surgical Anatomy* is better known in Scotland. It is an accurate and comprehensive work.

Landmarks, Medical and Surgical. By LUTHER HOLDEN, F.R.C.S. Fourth edition. 1888. 3*s.* 6*d.* London: J. & A. Churchill.

Surgical Applied Anatomy. By F. TREVES, F.R.C.S. Pp 574. 7*s.* 6*d.* London: Cassell and Co. 1894.

Human Osteology. By LUTHER HOLDEN, F.R.C.S. Edited by Professor Stewart and Robt. W. Reid. M.D. Seventh edition. With 59 Plates. 16*s.* London: J. & A. Churchill. 1887.

Tablets of Anatomy. By THOMAS COOKE, F.R.C.S.—These tablets are designed to help the student to retain what he has acquired in studying either in dissection or from the text-books. A new edition, abundantly illustrated and containing full digests of the results of recent anatomical investigations, will be published in October. London: Longmans, Green, and Co.

PHYSIOLOGY.

Text-book of Physiology. By Professor MICHAEL FOSTER, M.D., F.R.S. Four parts. Pp. 1550. With an Appendix. *The Chemical Basis of the Animal Body*, constituting a separate volume of 270 pages, by A. SHERIDAN LEA, D.Sc., F.R.S. The best English text-book of the subject; suitable for students preparing for higher examinations. Deals with histology as well as with physiology proper. The parts can be bought separately. Part I., The Blood, Tissues of Movement, and Vascular Mechanism. 10*s.* 6*d.* Part II., The Tissues of Chemical Action and Nutrition. 10*s.* 6*d.* Part III., The Central Nervous System. 7*s.* 6*d.* Thoroughly revised and brought up to present date. Part IV., The Tissues and Mechanisms of Reproduction. 10*s.* 6*d.* Appendix, 7*s.* 6*d.* Sixth edition. London: Macmillan and Co. 1895.

An Introduction to Human Physiology. By AUGUSTUS WALLER, M.D., F.R.S.—A very complete manual, though of medium size; thorough and attractively written in all its parts; presupposes good acquaintance with chemistry and physics; well suited to meet medical and other examinations in the subject, but containing very little histology; illustrated. Third edition. 1896. Pp. 640. London: Longmans, Green, and Co. Price 18*s.*

A Manual of Physiology for Students and Practitioners. By Professor G. N. STEWART, M.A., D.Sc., M.D., D.P.H.

Digitized by Google

Camb —A first-class text-book of medium size; profusely illustrated; deals fully with medical physiology; contains a number of practical exercises; also some well-coloured histological plates; thoroughly commendable. Pp. 795. London: Baillière, Tindall and Cox. 1895. Price 15*s*.

Kirkes' Handbook of Physiology. Edited by W. D. HALLIBURTON, M.D, F.R.S.—This book may be regarded as a thoroughly reliable exposition of the present state of physiological knowledge. Fourteenth edition. Revised. London: J. Murray. 1896. 14*s*.

Human Physiology. By Professor LANDOIS. Translated and edited by WILLIAM STIRLING. M.D., D Sc. Useful for reference; not suitably arranged for the student; requires much bringing up to present date. Two vols. Pp. 1120. 42*s*. With 845 illustrations. Fourth edition. London: Charles Griffin and Co. 1891.

Text-book of Physiology. By JOHN GRAY MCKENDRICK, M.D., F.R.S. A large work, containing in some directions more than the student requires, but a first-class treatise. 40*s* Two vols. Glasgow: Maclehose and Sons.

Manual of Physiology. By G. F. YEO, M.D., F.R.S. A good book, somewhat smaller than the foregoing. 14*s*. Third edition. London: J & A. Churchill. 1893.

Elements of Human Physiology. By ERNEST H. STARLING, M.D., M.R.C P., Joint Lecturer on Physiology at Guy's Hospital. Second edition, with 126 Engravings. 7*s*. 6*d*. London: J & A Churchill. 1895. Outlines; no histology.

Physiology for Beginners. By Professor MICHAEL FOSTER, M.D., F.R.S, and LEWIS E. SHORE, M.A., M.D.—A capital little book, forming a good introduction to Foster's "Text-book" or to Waller's "Human Physiology." Extremely clearly written and thoroughly illustrated. Not sufficient by itself to meet the requirements of medical examinations in physiology or histology. 2*s*. 6*d*. London: Macmillan and Co. 1894.

PHYSIOLOGICAL CHEMISTRY.

A Text-book of the Physiological Chemistry of the Animal Body. By ARTHUR GAMGEE, M.D. Edin., F R.S. Two volumes at present issued. Vol. I., Blood, Muscle, and Nerve; Vol. II., Digestion —The best manual on the subject, but only suitable for advanced students. Vol. III. still wanting. The volumes can be bought singly, 18*s*. each. London: Macmillan and Co. 1892.

Text-book of Chemical Physiology and Pathology. By Professor W. D. HALLIBURTON, M D., F.R.S —An excellent manual for all students. Illustrated. One vol. 8*s*. London: Longmans, Green, and Co 1891.

Essentials of Chemical Physiology. By the same author.—An excellent and indispensable manual for students in the physiological laboratory. It is a very handy size, 170 pp. Price 5*s* Longmans, Green, and Co. 1893.

The Chemical Basis of the Animal Body. By A. SHERIDAN LEA, D.Sc, F.R.S —A first-rate treatise, constituting the appendix to Foster's Physiology. Smaller, less illustrated, and less expensive than either of the foregoing, containing very complete references to original papers. One vol. Pp. 270. 7*s*. 6*d*. London: Macmillan and Co. 1892.

HISTOLOGY AND EMBRYOLOGY.

Some physiological text-books deal with Histology sufficiently fully for the pass examinations of the medical student; such books are Foster, Landois, and Kirkes (see above). The histological descriptions in Quain's "Anatomy" are unsurpassed. Special treatises are:—

A Course of Practical Histology. By E. A. SCHÄFER, F R.S., Jodrell Professor of Physiology in University College, London; Editor of the Histological Portion of Quain's "Anatomy." Second edition. Revised and enlarged. 1897. 7*s*. 6*d*. London: Smith, Elder, and Co.

The Elements of Embryology. By Professor MICHAEL FOSTER, F.R S, and the late Professor FRANK BALFOUR, F.R.S. Second edition, revised. Pp. 470. 1893. Eminently practical; the best book for those examinations in which practical work and manual skill in the subject are required.—*Practical Physiology*. By Professors MICHAEL FOSTER, F R S, and J. N. LANGLEY, F R.S. Sixth edition. 1895. An excellently selected series of laboratory exercises, with full instructions to the student. Both, London: Macmillan and Co.

Outlines of Practical Physiology. By Professor WILLIAM STIRLING, D.Sc. Third edition. 1895. 12*s* 6*d*. Thoroughly revised and partly re-written, with additional illustrations. Includes chemical and experimental physiology and references to practical medicine; histology not included; the best students' book on the subject; full of information and capitally illustrated.—*Outlines of Practical Histology*. Second edition. 1892 12*s*. 6*d*. Companion volume to the above and equally good; copiously illustrated. Both, London: Charles Griffin and Co.

Text-book of Histology. By A. CLARKSON, M.B., C.M. Edin. A useful student's book, with 200 excellent illustrations, most of them well coloured. Bristol: Wright. 1896. 21*s*.

Atlas of Human Anatomy. By Dr. ARNOLD BRASS, Göttingen. Translated by R. A. YOUNG, M.D., B.Sc. Sixty plates, containing 500 accurately coloured drawings of sections. London: Baillière, Tindall, and Cox. 1897. 31*s*. 6*d*.

Elements of Histology. By KLEIN. 7*s*. 6*d*. London: Cassell and Co.

There are also two small books dealing with histological methods which will be found useful by students and hospital residents:—

Methods and Formulæ. By PETER WYATT SQUIRE. 1892 London: J & A. Churchill.

Section Cutting and Staining. By W. S. COLMAN, M.D. Second edition, revised. 1896 London: H. K. Lewis.

CHEMISTRY AND PHYSICS.

Chemistry: General, Medical, and Pharmaceutical. By JOHN ATTFIELD, F.R.S —A very serviceable manual both for preparation work and reference. It has been designed especially for medical and pharmaceutical students, treats at fair length of both inorganic and organic chemistry, and contains useful data on the analysis and examination of drugs and morbid products—as, for example, calculi, urine, and blood. Fifteenth edition. 1893. 15*s*. London: Gurney and Jackson.

Organic Chemistry. By IRA REMSEN.—A clear account of the principles, including also the preparation of important organic substances. 6*s*. 6*d*. London: Macmillan and Co.

Notes on Analytical Chemistry for Students of Medicine. By A. J. BERNAYS —This is an excellent laboratory book for medical students preparing for examination, and contains also data of service to the practitioner—as, for example, the methods of examination of urinary deposits, the estimation of sugar, and the detection of biliary constituents, &c., in urine. Third edition. 1889. Pp. 150. 4*s*. 6*d*. London: J. & A. Churchill.

Practical Organic Chemistry. By S. RIDEAL, D.Sc.—A very handy little book for use in the laboratory. It covers all the ground of the London synopsis. 2*s*. 6*d*. London: H. K. Lewis.

Physics for Students of Medicine. By ALFRED DANIELL, M.A., D.Sc.—This is a recently published work by Professor Daniell, whose experience of the requirements of medical students in regard to physics is well known. It will be found an excellent companion to lecture work and is suitable for students preparing for the elementary physics examination of the Conjoint Board. It is published by Macmillan and Co., price 4*s*. 6*d*. For the first M.B. Lond. students should possess a copy of the more advanced work—*A Text-book of Physics*—by the same author and publisher.

A Manual of Physics. By WILLIAM PEDDIE, D.Sc., F.R.S.E. Second edition (revised and enlarged). London: Baillière, Tindall, and Cox. 1896. Price 7*s*. 6*d*.—This handy-sized volume will be found a very useful companion to those reading for the London University examinations and the Conjoint Board. It belongs to the University series. It is written to the level of junior students or of schoolboys of a fair average intelligence, but for that reason, we think, might have been more fully illustrated.

Elementary Lessons in Electricity and Magnetism. By SYLVANUS THOMPSON, D.Sc. A standard text-book on the subject. 4*s*. 6*d*. London: Macmillan and Co.

MATERIA MEDICA AND THERAPEUTICS.

Text-book of Pharmacology, Therapeutics, and Materia Medica. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S. Third edition, containing the additions (1891) to the British Pharmacopœia, 21*s*.; in two vols., 22*s*. 6*d*. Supplement separately, 1*s*.—The student for the higher examinations would be well advised to provide himself with this work. It is equally useful as a practical treatise and as a work of reference and is admirably written. It is not intended for junior students.

A Handbook of Therapeutics. By SIDNEY RINGER, M.D., F.R.C.P., F.R S. This is another large and important work, designed more for reference than for daily use. Thirteenth edition. London: H. K. Lewis.

Digitized by Google

Materia Medica. By HALE WHITE, M.D., F.R.C.P., Physician to Guy's Hospital. Second edition. 1897 London: J. & A. Churchill. 7*s.* 6*d.*—*The Handbook of Pharmacology, Materia Medica, and Therapeutics.* By J. MITCHELL BRUCE, M.D., F.R.C.P. Thirty-first thousand. Pp. 582. London: Cassell and Co. 1896.—Two excellent practical books for students engaged in any of the pass examinations.

Essentials of Materia Medica and Therapeutics. By Sir A. B. GARROD, M.D., F.R.S., &c. Fourteenth edition. 1895. Edited by NESTOR TIRARD, M.D., F.R.C.P. The subject is regarded entirely from a practical therapeutic point of view, and the work, though more useful to the practitioner, can still be used as a book of reference by the student. 12*s.* 6*d.* London: Longmans, Green, and Co.

Of other text-books likely to be of value we might mention:—*Materia Medica and Therapeutics: Inorganic Substances.* By C. D. F. PHILLIPS, M.D. Second edition. 8vo. 1894. Pp. 898. 21*s.* London: J. & A. Churchill.—*Guide to Therapeutics.* By R. FARQUHARSON, M.D., F.R.C.P., &c. Fifth edition. Pp. 417. 7*s.* 6*d.* London: Smith, Elder, and Co. 1891.—*Materia Medica and Therapeutics.* By Dr. BARTHOLOW. Eighth edition. Pp. 866. 21*s.* London: H. K. Lewis. 1896.—*The Dictionary of Treatment.* By WM. WHITLA, M.D. Q.U.I. Third edition. Pp. 1000. 16*s.* London: Henry Renshaw. 1894. A capital, practical book, and pleasant reading.—*Notebook on Materia Medica.* By SCORESBY JACKSON. New edition. Edited by RALPH STOCKMAN, M.D., and J. RUTHERFORD HILL. London: J. Thin.

MEDICINE.

The number of text-books on Medicine is so large, and their general excellence so high, that it is impossible to make a selection with which no one could find legitimate fault. It must always appear that some books as good or better than the specified list have been omitted. We do not for a moment pretend that this is the best possible list, but the student who is guided by these books will be in very good hands.

The list might be considerably extended were works dealing with special branches of medicine included. To the aspirant for high medical degrees it may be a matter of moment to make himself familiar with some of these, such as Gowers on the Nervous System, Ashby and Wright on Diseases of Children, Washbourn and Goodall on Fevers; whilst he would find it valuable to refer to special treatises on diseases of the throat, dermatology, and other branches of medicine when engaged in the practical study of the subject. But our purview is not intended to embrace the whole field of medical literature, and the library of the medical school will afford him ample opportunity for consulting such works if need be. His own library should consist of a few selected general text-books, with the contents of which he should make himself thoroughly familiar.

Text-book of the Principles and Practice of Medicine. By the late HILTON FAGGE, M.D., F.R.S., and P. H. PYE-SMITH, M.D., F.R.C.P., F.R.S. Third edition. 1891. Pp. 2209. 40*s.* London: J. & A. Churchill. Two vols.—A work of great interest mainly based on the author's personal experience as physician to Guy's Hospital as well as his wide knowledge of the literature of medicine. It is almost indispensable to the advanced student.

A System of Medicine by Many Writers. Edited by T. CLIFFORD ALLBUTT, M.A., M.D. Cantab., LL.D. Glasg., F.R.C.P. Lond., F.R.S., F.L.S., F.S.A., Regius Professor of Physic in the University of Cambridge. Six vols. Each 25*s.* London: Macmillan and Co.—Three volumes of this admirable work have now appeared. In scope and character it resembles the well-known "System" edited by the late Dr. Russell Reynolds. The articles are replete with information and embrace the latest teachings of science. It should be invaluable to the practitioner as well as to the candidate for higher degrees.

The three following American works are of high class and represent the best teaching of the day.

A Text-book of the Theory and Practice of Medicine By American Teachers. Edited by WILLIAM PEPPER, M.D., LL.D. Two vols. 1893. Pp. 909 and 1046. Philadelphia: W. B. Saunders. London: The Rebman Co.

The Practice of Medicine. By JAMES TYSON, M.D. 1896. Pp. 1184. Philadelphia: Blakiston. Manchester: J. K. King and Son.

The Practice of Medicine. By HORATIO C. WOOD, A.M., M.D., LL.D., and REGINALD H. FITZ, A.M., M.D. 1897. Pp. 1088. London and Philadelphia: J. B. Lippincott Co.

The Theory and Practice of Medicine. By J. S. BRISTOWE, M.D., F.R.S. Seventh edition. 1890. Pp. 1285. 21*s.* London: Smith, Elder, and Co.—A work of sterling merit by a highly-esteemed physician; perhaps more full in clinical and pathological exposition than in therapeutical, but thoroughly sound in teaching.

The Theory and Practice of Medicine. By F. T. ROBERTS, M.D. Ninth edition. 21*s.* London: H. K. Lewis.—Long a deserved favourite with students, for whom it is especially written. Its great feature is the remarkably systematic division of the subject matter; replete with facts, but somewhat restrained in style.

The Principles and Practice of Medicine. By W. OSLER, M.D. Second edition. 1895. Pp. 1143. 24*s.* London: Young J. Pentland.—This work is one of the best text-books now available; it is clearly and pleasantly written, and is thoroughly up to date in science and practice.

Manual of the Practice of Medicine. By F. TAYLOR, M.D., F.R.C.P. Fourth edition, with Thirty Engravings. 1895. Pp. 932. 15*s.* London: J. & A. Churchill.—Perhaps the most widely read of all text-books in the present day, sharing with Osler's work the favour of the student, who is fortunate to have such sound and useful works at his disposal.

Text-book of Medicine. By Professor STRÜMPELL. Second edition. 1893. Pp. 1053. 28*s.* London: H. K. Lewis.—A work of great merit, representing the German school; in originality nearly approaching to the famous text-book of Niemeyer, which was highly appreciated twenty years ago.

Dictionary of Medicine. Edited by Sir RICHARD QUAIN, Bart., M.D. Lond., LL.D. Edin., F.R.S., assisted by F. T. ROBERTS, M.D., F.R.C.P., and J. MITCHELL BRUCE, M.D., F.R.C.P. Two vols. 1895. 40*s.* nett. London: Longmans, Green, and Co.—The arrangement of this work is such that the subjects can be readily selected for study, and the thorough revision to which it has been subjected renders it in all respects a trustworthy guide. The contributors are all of them physicians well qualified to speak on the subjects assigned them.

Dictionary of Practical Medicine. By J. K. FOWLER, M.D., F.R.C.P. 1890. Pp. 942. 21*s.* London: J. & A. Churchill.—A very useful book of reference for the student and busy practitioner.

Elements of Practical Medicine. By A. H. CARTER, M.D., F.R.C.P. Seventh edition. 1895. Pp. 496. 10*s.* London: H. K. Lewis.

Student's Guide to Practice of Medicine. By M. CHARTERIS, M.D., L.R.C.S. Edin., &c. Seventh edition. With Engravings. 1894. Pp. 712. 10*s.* London: J. & A. Churchill.

An Index of Medicine: a Manual for the Use of Senior Students and Others. By SEYMOUR TAYLOR, M.D., M.R.C.P., Senior Assistant-Physician to the West London Hospital. With Illustrations. Pp. 808. 12*s.* 6*d.* London: Smith, Elder, and Co.—The foregoing works are well planned; without being exhaustive, they present the salient facts of medicine in a concise form, and may well be chosen by the beginner.

Medical Diagnosis. By J. M. DA COSTA, M.D., LL.D. Eighth edition. 1896. London: Smith, Elder, and Co.—The leading text-book on diagnosis, replete with practical information.

Medical Diagnosis. By J. H. MUSSER, M.D. 1894. Edinburgh and London: Young J. Pentland.—A voluminous work, less practical than Da Costa's treatise, and resembling rather a systematic manual of medicine, confined to diagnostic points.

Clinical Medicine. By JUDSON BURY, M.D., F.R.C.P. Price 21*s.* London: Charles Griffin and Co.—A very admirable and clearly written work, fully illustrated.

Clinical Manual. By JAMES FINLAYSON, M.D., F.F.P.S. Glasg. Third edition. 1891. Pp. 719. 8*s.* 6*d.* London: Smith, Elder, and Co.—One of the earliest works of its class, thorough and systematic.

Manual of Medical Diagnosis. By Professor H. VIERORDT. With 178 Engravings, many in colour. 1892. Pp. 700. 18*s.* Edinburgh and London: Young J. Pentland.—A translation of a systematic work on diagnosis, which has just reached a fifth edition in the original.

Medical Diagnosis: A Manual of Clinical Methods. By J. J. GRAHAM BROWN, M.D., F.R.C.P., F.R.S. Edin.

Digitized by Google

Third edition. 1887. Pp. 380. 10*s.* 6*d.* Edinburgh: Bell and Bradfute.—A sound and reliable manual.

Fenwick's Students' Guide to Medical Diagnosis. Edited by W. SOLTAU FENWICK, M.D. Seventh edition. With 117 Engravings. 1891. Pp. about 500. 7*s.* London: J. & A. Churchill.—This manual has long enjoyed undivided favour; an excellent guide for practical clinical work.

Physical Diagnosis: A Guide to Methods of Clinical Investigation. By G. A. GIBSON, M.D., F.R.C.P. Edin., and WILLIAM RUSSELL, M.D., F.R.C.P. Edin. Second edition. With 109 Illustrations, many coloured. 1893. Pp. 383. 10*s.* 6*d.* Edinburgh and London: Young J. Pentland.—Contains a good exposition of the rationale of the physical signs of disease.

Auscultation and Percussion. By SAMUEL J. GEE, M.D., F.R.C.P. Fourth edition. 1893. Pp. 327. 6*s.* London: Smith, Elder, and Co.—An original and helpful manual for the clinical observer.

Cardiac Outlines. By WILLIAM EWART, M.D., F.R.C.P. With 62 Illustrations. 1892. Pp. 165. 5*s.* 6*d.* London: Baillière, Tindall, and Cox.—Useful as a guide to the thorough examination of cardiac disease and the record of physical signs.

Clinical Diagnosis. By Professor R. VON JAKSCH. Second edition. Translated and edited by JAMES CAGNEY, M.D., M.R.C.P. 25*s.* London: Charles Griffin and Co.—A work of world-wide reputation, dealing exhaustively with microscopical and chemical aids to diagnosis.

A Manual of Clinical Diagnosis. By CHARLES E. SIMON, M.D. 1896. London: Henry Kimpton.—Covers the same ground as the classical treatise of von Jaksch; admirably suited for the clinical laboratory.

Guide to Examination of Urine. By J. WICKHAM LEGG, M.D., F.R.C.P. Seventh edition. 1893. Pp. 136. 3*s.* 6*d.* London: H. K. Lewis.

Notes on Examination of Blood and Excreta. By SIDNEY COUPLAND, M.D., F.R.C.P. Third edition. 1892. Pp. 64. 1*s.* 6*d.* London: H. K. Lewis.—Examples of a large class of small and concise manuals intended to assist the ward clerk in his daily observations.

SURGERY.

The standard English text-book on Surgery for the student is the tenth edition of *Erichsen's Science and Art of Surgery*. It has been brought well up to date. It is comprehensive, but not diffuse, and no student will ever regret having mastered it. *Holmes's Treatise on Surgery* (edited by Pickering Pick) is also a trustworthy manual, though somewhat smaller; the style is very clear. *Walsham's Theory and Practice of Surgery*, though useful for a student commencing the study of the subject, and sufficiently full for the minor examinations in surgery, is by no means sufficient for any of the higher examinations. It is careful and exact. There are several larger treatises on surgery suitable for the more advanced student; of these the latest is *Treves's System of Surgery*; it is excellently printed, very accurate, and fully up to date. *Holmes and Hulke's System of Surgery*, though no recent edition of it has appeared, still remains valuable, as it contains numerous excellent authoritative monographs. *Heath's Dictionary of Practical Surgery* is also useful for reference. For Operative Surgery *Jacobson's Operations of Surgery* is an admirable text-book. The information given includes, in addition to the descriptions of the operations, the reasons for their performance. *Treves's Manual of Operative Surgery* is also excellent, and one of the two should be read by all candidates for any of the higher examinations. *Treves's Student's Handbook of Surgical Operations* gives a short but careful account of the ordinary operations, and is well worth using as a text-book in a course of operative surgery. There are numerous other works on surgery, such as those of Bryant, Mansell Moullin, Druitt, Keetley, and Gant; all these deservedly have their adherents. Both Heath and Pearce Gould have written useful little treatises on Surgical Diagnosis. Minor Surgery and Bandaging may be studied in the works of Heath, Caird and Cathcart, or Berkeley Hill.

The Science and Art of Surgery. By Sir J. E. ERICHSEN, F.R.S., LL.D. Tenth edition. Edited by the late MARCUS BECK, M.S., F.R.C.S., and RAYMOND JOHNSON, B.S., F.R.C.S. 1895. With nearly 1000 Wood Engravings. Two vols. 48*s.* London: Longmans, Green, and Co.

Treatise on Surgery. By T. HOLMES, F.R.C.S., &c. Fifth edition. 1888. Pp. 1004. 30*s.* London: Smith, Elder, and Co.

Surgery: its Theory and Practice. By W. J. WALSHAM, F.R.C.S., &c. Sixth edition. 1895. With 400 Engravings. Pp. 800. 12*s.* 6*d.* London: J. & A. Churchill.

A System of Surgery. Edited by FREDERICK TREVES, F.R.C.S. 1895. With four Coloured Plates and numerous Illustrations. 48*s.* London: Cassell and Co.

A System of Surgery. Edited by TIMOTHY HOLMES, F.R.C.S., and J. W. HULKE, F.R.C.S., F.R.S. Third edition. Three vols. With Coloured Plates and numerous Illustrations. Price £4 4*s.* London: Longmans, Green, and Co.

Dictionary of Practical Surgery. By C. HEATH, F.R.C.S. Third edition. 1889. Two vols. Vol. I, pp. 978; Vol. II., pp. 884. 32*s.* London: Smith, Elder, and Co.

Surgery. By C. W. MANSELL MOULLIN, F.R.C.S. 1891. With 497 Engravings. Pp. 1413. 34*s.* London: J. & A. Churchill.

Manual of Practice of Surgery. Two vols. By T. BRYANT, M.D., F.R.C.S. Fourth edition. 1884. With 750 Engravings. Pp. 1520. 32*s.* London: J. & A. Churchill.

Manual of Surgery. By F. TREVES, F.R.C.S. 1894. Pp. 574. Three vols. 22*s.* 6*d.* London: Cassell and Co.

Druitt's Surgeon's Vade-Mecum. Edited by STANLEY BOYD, F.R.C.S. Twelfth edition. With 373 Engravings. Pp. 1000. 16*s.* London: J. & A. Churchill.

Index of Surgery. By C. R. B. KEETLEY, F.R.C.S., &c. Fourth edition. 1887. Pp. 526. 10*s.* 6*d.* London: Smith, Elder, and Co.

Operative Surgery. By F. TREVES, F.R.C.S. 1894. Pp. 1550. 42*s.* London: Cassell and Co.

The Operations of Surgery. By W. H. A. JACOBSON, F.R.C.S. Third edition. 1897. Pp. 1337. 34*s.* London: J. & A. Churchill.

Senn: Principles of Surgery. By N. SENN, M.D., Ph.D. Second edition. One vol., Pp. 656. With 178 fine wood Engravings and Coloured Plates. 24*s.* 6*d.* London: The Rebman Publishing Company.

Surgical Operations. By A. E. J. BARKER, F.R.C.S. With 61 Wood Engravings. 12*s.* 6*d.* London: Longmans, Green, and Co.

The Science and Practice of Surgery: a Complete Text-book. By F. J. GANT, F.R.C.S., Senior Surgeon, Royal Free Hospital. Third edition, about 1100 Engravings. Two vols. Price 36*s.*

Guide to Surgical Diagnosis. By C. HEATH, F.R.C.S. Second edition. 1883. Pp. 240. 6*s.* 6*d.* London: J. & A. Churchill.

Student's Guide to Surgical Diagnosis. By A. P. GOULD, F.R.C.S., &c. Pp. 584. London: Cassell and Co.

Minor Surgery and Bandaging. By C. HEATH, F.R.C.S. Eleventh edition. 1894. With 158 Engravings. Pp. 389. 6*s.*

A Surgical Handbook. By CAIRD and CATHCART. With Illustrations. Seventh edition. 1896. 8*s.* 6*d.* London: Griffin and Co.

A Text-book of Surgery. Edited by WILLIAM W. KEEN, M.D., LL.D., and J. WILLIAM WHITE, M.D., Ph.D. Third edition. In two parts. Profusely illustrated with Coloured and Black and White Plates. Price 42*s.* London: The Rebman Publishing Company.

MIDWIFERY.

In this subject the student will find it advantageous to have two books; one a small and elementary work, which he can, if he likes, take with him when attending his cases; and the other a larger text-book, for systematic reading.

Of the elementary books we mention four:—

First Lines of Midwifery. By G. ERNEST HERMAN, M.B., F.R.C.P. 1897. London: Cassell and Co.—*Obstetric Aphorisms for Students.* By J. G. SWAYNE, M.D. Tenth edition. Fcap. 8vo, with Twenty Engravings. 3*s.* 6*d.* 1893. London: J. & A. Churchill.—*An Introduction to Midwifery.* By ARCHIBALD DONALD, M.D.—*A short Practice of Midwifery.* By HENRY JELLETT, M.D.—All four are excellent for their purpose—that is, they serve well to instruct the student as to his practical duties and the points to be noted and watched in attending his first cases of labour. Dr. Swayne's book is the old-established favourite. The other two are more modern, but by any of them the student will find himself much fortified.

General Text-books:—

A Manual of Midwifery. By A. L. GALABIN, M.D., F.R.C.P.—A very deservedly popular book; literally a manual as it is in one volume; clear and precise and sufficiently informatory to provide the student with all the information necessary for pass examinations. Fourth edition.

Digitized by Google

Crown 8vo. 1893. With 271 Engravings. 15*s*. London: J. & A. Churchill.

The Science and Art of Midwifery. By W. T. LUSK, M.D.—This American work is undoubtedly in many ways the best English text-book on the subject. The amount of information contained is very large, the references complete, and the plan of the book is easy to follow. For honour examinations this book is a necessity. Fourth edition. 1892. Pp. 671. 18*s*. London: H. K. Lewis.

The Science and Practice of Midwifery. By W. S. PLAYFAIR, M.D., F.R.C.P. Eighth edition. Two volumes, each containing 430 and 443 pages respectively.—This has long been a deservedly popular work with students. It practically held the field till the appearance of the two previous treatises, and is still, and we think fitly, the most widely read text-book on the subject. Two vols. Eighth edition. 1893. 28*s*. London: Smith, Elder, and Co.

The student will also find the following books of reference of use:—

Text-book of Midwifery. By the late OTTO SPIEGELBERG. Translated from the second German edition by Dr. HURRY.—This work in two volumes is published by the New Sydenham Society. Although a text-book in name it is not well adapted to the immediate needs of the student, who, however, may be advised to consult it on special points.—*Difficult Labour*, by G. ERNEST HERMAN, M.B., F.R.C.P., will also be found a useful work of reference on its subject.

GYNÆCOLOGY.

A Manual of Gynæcology. By BERRY HART, M.D., and FREHLAND BARBOUR, M.D.—The work consists of two parts and an appendix. Part I. deals with the Anatomy, Physiology, and Methods of Examination of the Female Pelvic Organs, and Part II. with the diseases peculiar to the organs. This favourite manual is especially strong in its anatomical and purely scientific sections, if somewhat less complete as a clinical guide. It has the advantage of giving at the end an Index of Recent Gynæcological Literature. Fourth edition. Pp. 722. Illustrated with Lithographs and 400 Woodcuts. London: W. & A. K. Johnston.

The Student's Guide to the Diseases of Women. By A. L. GALABIN, M.D., F.R.C.P.—A small book that has been useful to several generations of students and will be useful to generations more. Fifth edition. 1893. Pp. 507. 8*s*. 6*d*. London: J. & A. Churchill.

A Practical Text-book of the Diseases of Women. By ARTHUR H. N. LEWERS, M.D.—This is also a small book, but somewhat larger than the above, and treats the subject rather more from the clinical point of view. It is a deservedly popular work with the students because of the extremely practical nature of its information. Fifth edition. 1893. Pp. 439. 10*s* 6*d*. London: H. K. Lewis.

The following books of reference are recommended:—*Clinical Gynæcology*. By T. MORE MADDEN, M.D. This book consists of forty-seven lectures on the diseases of women and may be usefully consulted on special points.—*A Treatise on Gynæcology*. By S. POZZI, M.D. This work, in three volumes, is published by the New Sydenham Society, and while not well adapted for general reading will be found invaluable for reference. The same remark to a greater or less extent, applies to the following books:—*Diseases of the Ovaries*. By LAWSON TAIT, F.R.C.S. Fourth edition. 1883.—*Abdominal Surgery*. By J. GREIG SMITH. Third edition. 1889.—*The Surgical Diseases of the Ovaries and Fallopian Tubes*. By J. BLAND SUTTON, F.R.C.S.—*The Diagnosis and Surgical Treatment of Abdominal Tumours*. By Sir SPENCER WELLS.—*Clinical Lectures on the Diseases of Women*. By J. MATTHEWS DUNCAN, M.D. Fourth edition. 1890.—*The Diseases of Women and their Treatment*. By H. MACNAUGHTON JONES, M.D., F.R.C.S.I., F.R.C.S.E. Sixth edition.

DISEASES OF CHILDREN.

It is only natural that students should be obliged by the medical schools to give some attention to the study of the diseases of children when it is considered that in general practice one patient at least out of every three will be a child. At present some of the examining boards, as the Royal University of Ireland, require candidates for the M.B. degree to produce certificates of having attended a practical course on the diseases of children, and the students are also specially examined in this subject. We therefore suggest for their guidance the following text-books:—*Diseases of Children, Medical and Surgical*. By HENRY ASHBY, M.D., F.R.C.P., and G. A. WRIGHT, B.A., M.B., F.R.C.S. Eng. Enlarged and improved edition, with 192 Illustrations. 8vo. Pp. 248. 25*s*. London: Longmans, Green, and Co. This admirable work, as it deals with diseases of children from both a medical and surgical point of view, can be recommended to students as containing everything that they will require to know.—*The Diseases of Children*. By JAMES F. GOODHART, M.D., F.R.C.P. Fifth edition. Pp. 740. 1894. 10*s*. 6*d*. London: J. & A. Churchill. For those who want to study diseases of children from a medical aspect we can recommend this most popular manual, written, as it is, by one who convinces the reader that he has seen everything he describes.—*The Diseases of Children (Medical)*. By H. BRYAN DONKIN M.D., F.R.C.P. Medium 8vo. 16*s*. London: Charles Griffin and Co. This is in many respects a most original book.—For those students who desire to know the surgical aspect of the affections of children there are two useful text-books, *Surgical Diseases of Children*, by E. OWEN, M.B., F.R.C.S. Eng., price 21*s*., Cassell and Co., Limited, London, Paris, and New York; and *The Surgical Diseases of Children and their Treatment by Modern Methods*, by D'ARCY POWER, M.A., M.B. Oxon., F.R.C.S. Eng., crown 8vo, price 10*s*. 6*d*. London: H. K. Lewis.—A manual which is used a good deal by Edinburgh students is *Disease in Children*, by JAMES CARMICHAEL, M.D., F.R.C.P. Ed. Crown 8vo. Pp. 520. Price 10*s*. 6*d*. Young J. Pentland: Edinburgh and London.—The following larger works are recommended for reference:—EUSTACE SMITH'S *Treatise on Disease in Children*. Second edition. Price 22*s* 1889. 8vo. Pp. 895. London: J. & A. Churchill.—*Lectures on Children's Diseases*. By HENOCH. Two vols. Translated by JOHN THOMPSON, M.B., F.R.C.P. Ed., from the fourth German edition. This treatise is published by the New Sydenham Society.—*Diseases of Children*. Edited by LOUIS STARR, M.D., and sixty Associates. Two vols. Price 42*s*. London: The Rebman Publishing Co. This is one of the most recent large works on diseases of children compiled in America. It is well got up and profusely illustrated.—*Pediatrics: The Hygienic and Medical Treatment of Diseases in Children*. By THOMAS MORGAN ROTCH, M.D., Professor of Diseases of Children, Harvard University. Two vols. Pp. 1124. Price 25*s*. net.—Two other very useful books are those of Dr. CHEADLE: *On the Principles and Exact Conditions to be Observed in the Artificial Feeding of Infants* (London: Smith, Elder, and Co., price 5*s*.), and Dr. LOUIS STARR: *Hygiene of the Nursery* (Sixth edition, crown 8vo, 3*s*. 6*d*. London: H. K. Lewis).

OPHTHALMOLOGY.

Either of the two following handbooks on Ophthalmology will be found to contain all that is necessary to the student of medicine who has no inclination to make a special study of the subject.

Handbook of Diseases of the Eye. By HENRY R. SWANZY, M.B., F.R.C.S.I. Sixth edition. Pp. 608. 1897. An excellent book. Price 12*s*. 6*d*. London: H. K. Lewis, 136, Gower-street.

The Diseases of the Eye. By EDWARD NETTLESHIP, F.R.C.S. Fifth edition. 1890. Student's Guide Series. Price 7*s*. 6*d*. Fcap. 8vo. London: J. & A. Churchill.

By those who wish for fuller information on the subject the larger text-books must be consulted, of which, perhaps, *The Text-book of Ophthalmology*, by Professor FUCHS, of the Vienna University, is the most generally useful. This has been recently translated from the German into English by A. DUANE, and is published in one large octavo volume, with 178 Illustrations, price 21*s*., by H. K. Lewis, 136, Gower-street.

Most students find the study of errors of refraction difficult and unattractive and are consequently inclined to neglect this important branch of the subject. *The Manual for Students on the Refraction of the Eye*, by GUSTAVUS HARTRIDGE, is a most useful little book, as it explains simply the principles on which are based the methods in use in the out-patient department.

It is unnecessary, and, indeed, undesirable, here to enumerate all the text-books which have been written on diseases of the eye, but the following may be mentioned as generally useful books:—

Diseases of the Eye. By GEORGE BERRY, M.B., F.R.C.S. Edin. Edinburgh and London: Young J. Pentland.

Handbook of Ophthalmic Science and Practice. By HENRY JULER, F.R.C.S.

The Fundus Oculi. By W. ADAMS FROST, F.R.C.S. An

Digitized by Google

excellent book with admirable illustrations. Price £3 3s. Edinburgh and London: Young J. Pentland.

The Refraction of the Eye. A manual for students. By GUSTAVUS HARIDGE, F.R.C.S., Surgeon to the Royal Westminster Ophthalmic Hospital. Eighth edition. With 100 Illustrations, test types, &c. Pp. 259. Crown 8vo. 6s. 1896. Tenth thousand.

The Ophthalmoscope. A manual for students. Second edition. With 4 Coloured Plates and 67 Engravings. Pp. 156. Crown 8vo, 4s. 6d. 1894.

To those who are conversant with French the "Traité Complet d'Opthalmologie," by L. DE WECKER and E. LANDOLT, may be recommended as the most valuable work of reference. It is published in four large volumes at a price of about 20 francs each volume, and is consequently scarcely adapted for the student's use. A German edition of this work may also be obtained.

PATHOLOGY.

Manual of General Pathology. By JOSEPH FRANK PAYNE, M.D. Oxon., F.R.C.P. Pp. 702. 150 Illustrations.—Deals specially with general pathology and pathological anatomy and the processes and causes of disease, including parasites, both animal and vegetable. Special pathology and pathological histology are not touched upon, but on general pathology it is one of the best books in the language. London: Smith, Elder, and Co. 1888.

A Text-book of Pathology, Systematic and Practical. By Professor D. J. HAMILTON.—An admirably original, but somewhat unequal work. The most complete and systematic work published in the English language. Contains a very full and accurate bibliography. Invaluable for reference and for study for the higher examinations. Published in two volumes (the second volume is divided into two parts), which may be bought separately. Vol. I. (London: Macmillan and Co., 1889, pp. 736, 225 Illustrations, woodcuts, and coloured lithographs, price 21s. net) deals with the technique of the post-mortem room and the histological and bacteriological laboratories. An account is also given of the general pathological processes of the diseases of the blood, the heart and blood-vessels, and of tumours. Vol II., 1895, Part 1 (172 Illustrations, pp. 514, price 15s. net), treats of diseases of the air-passages and lungs, of the liver, of the genito-urinary appartus, and the alimentary tract, except the intestines, whilst Part 2 of Vol. II. (225 Illustrations, pp. 624, price 15s. net) completes the description of the diseases of the alimentary tract and then takes up in turn the nervous system (very good), diseases of the mamma, bones and joints, the skin, malformations, diseases of the fœtal membranes and placenta, vegetable and animal parasites, animal heat and fever.

A Text-book of Special Pathological Anatomy. By ERNST ZIEGLER. Translated and edited from the eighth German edition by DONALD MACALISTER, M.A., M.D., and HENRY W. CATTELL, M.A., M.D. Sections I.—VIII. 1896. London: Macmillan and Co.—A first instalment of a new English edition of a leading text-book notable for its excellent and abundant illustrations and full references to literature. A good text-book for the higher examinations. The subjects treated in this volume embrace the Blood and Organs of Circulation, the Osseous and Nervous Systems. The complete work (published by Fischer, of Jena) comprises a volume on General Pathological Anatomy, as well as the whole of Special Pathological Anatomy, of which the present volume constitutes about one-half.

A Manual of Pathology. By JOSEPH COATS, M.D. Pp. 1180. Numerous Illustrations. London: Longmans, Green, and Co. Third edition. 1895.—An interesting treatise on morbid anatomy and pathology; covers a great deal of ground; in most cases very reliable and a good text-book, especially for the student preparing for the higher examinations.

Practical Pathology. By GERMAN SIMS WOODHEAD, M.D., F.R.S.E. Third edition. 1892. Pp. 652. With 195 Coloured Plates from Original Drawings.—This book is almost an essential to the proper study of the subject. It is not only thoroughly clear and well arranged, but beautifully illustrated. The points where the student might be expected to be most in difficulty have received special attention. 25s. Edinburgh and London: Young J. Pentland.

An Introduction to Pathology and General Morbid Anatomy. By T. HENRY GREEN, M.D., F.R.C.P. Revised and enlarged by H. MONTAGUE MURRAY, M.D., F.R.C.P. 224 Engravings.—An excellent *résumé* of pathology from the student's point of view. Brought well up to date, especially in the sections dealing with inflammation, the specific infectious fevers, and the nervous system. May be confidently recommended as giving a very good and accurate account of the groundwork of pathology and as containing sufficient information to enable the student to pass any ordinary examination on the subject. Price 17s. London: Henry Renshaw.

Text-book of General Pathology and Pathological Anatomy. By Professor THOMA. Translated from the German by ALEXANDER BRUCE, M.A., M.D., F.R.C.P.E., F.R.C.S.E., Vol. I., with 436 Illustrations. London: Adam and Charles Black. 1896.—An admirable work for reference. Professor Thoma treats in this first volume of the natural history of disease, pays special attention to the questions of heredity and malformations, to the physics and mathematics of the laws of pathology, especially of the circulatory system.

A Text-book of Morbid Histology for Students and Practitioners. By RUBERT BOYCE, M.B., M.R.C.S. Pp. 477, with 130 Coloured Photographic Illustrations. 31s. 6d. London: H. K. Lewis. 1892.—Contains good descriptions of morbid histological specimens; also a number of photographs, which, however, are of very unequal merit and value. Exceedingly useful for the advanced student and the laboratory worker. A carefully selected bibliography is appended.

The Elements of Pathological Histology. By A. WEICHSELBAUM. Translated by W. R. DAWSON, M.D. 1895. London: Longmans, Green, and Co.—A work of approved merit, concise and clear in exposition; useful for practical study, and admirably illustrated.

The following books have different uses for students which we have tried to briefly indicate:—

Practical Pathology. By JOHN LINDSAY STEVEN, M.D. Pp. 266. Glasgow: James Maclehose and Sons. 1887.—A concise and well-arranged description of methods and of pathological anatomy and histology. There are no illustrations, but the descriptions are clear and concise. Useful for a student going in for examination or as a supplement to demonstrations.

Practical Pathology and Morbid Histology. By HENRAGE GIBBES, M.D. Pp. 320. Illustrated with 60 Photographic Reproductions. Edinburgh and London: Young J. Pentland. 1891.—A good practical book with a series of photographs of typical pathological microscopic specimens. Useful for private laboratory work rather than for examination purposes.

Surgical Pathology and Morbid Anatomy. By ANTHONY BOWLBY, F.R.C.S. Third edition. Pp. 640. London: J. & A. Churchill. 1895.—A capital little handbook on surgical pathology. Well up to date as regards pathogenesis.

Elements of Surgical Pathology. By AUGUSTUS J. PEPPER, M.S., M.B. Lond., F.R.C.S. Eng. Pp. 532. 99 Engravings. Fourth edition, re-written and enlarged. 8s. 6d. London, Paris, and Melbourne: Cassell and Co., Limited. 1894.—A compact little handbook of surgical pathology.

A Handbook of Surgical Pathology. By W. J. WALSHAM, M.B., F.R.C.S. Eng.; and D'ARCY POWER, M.A., M.B. Oxon., F.R.C.S. Eng. Pp. 634. London: Baillière, Tindall, and Cox. Second edition. 1890. Price 7s. 6d.—A clear and concise description of the specimens in the Museum of St. Bartholomew's Hospital, and therefore specially useful to students of that school or to those that have access to that museum. But the descriptions are so good that this work will serve as a capital text-book to any student preparing for an examination in surgical pathology.

Pathological Anatomy of Diseases. By NORMAN MOORE, M.D. London: J & A. Churchill. 1889. Fcap. 8vo. 8s. 6d.—An accurate and concise. but not very full, student's manual of morbid anatomy of 416 pages, with 110 figures.

Practical Morbid Anatomy. By H. D. ROLLESTON, M.A., M.D., F.R.C.P.; and A. A. KANTHACK, M.D., M.R.C.P. Cambridge University Press. Price 6s. 1894. Pp. 240.—A capital account of the methods and course of procedure to be adopted in the post-mortem room. Practical, but thoroughly scientific throughout.

Section Cutting and Staining. By WALTER S. COLMAN, M.B. Lond. London: H. K. Lewis. Second edition, just ready.—A handy little guide to the preparation of normal and morbid histological specimens. Concise, and gives everything that is really necessary for ordinary class work.

Digitized by Google

The following books are hardly to be used as text-books, but for one reason or another the student will do well to supplement his reading by consulting them :—

Lectures on Surgical Pathology. By Sir JAMES PAGET, Bart., F.R.S., &c. Revised and edited by Professor WM. TURNER, F.R.S. Pp. 844. 130 Illustrations. London : Longmans, Green, and Co. 1876. Fourth edition.—Still one of the most valuable books of reference on surgical pathology in our language, and should be read by every student as a model on which to base methods of observation and study.

An Introduction to General Pathology. By JOHN BLAND SUTTON, F.R.C.S. Pp. 390. 14*s*. London : J. & A. Churchill. 1886.—An admirable introduction to the subject of evolution in pathology, well worth study by those who wish to gain more than a mere examination knowledge of the subject.

Lectures on Pathological Anatomy. By SAMUEL WILKS, M.D., F.R.S., and the late WALTER MOXON, M.D., F.R.C.P. Third edition, thoroughly revised by SAMUEL WILKS, M.D., LL.D., F.R.S. London and New York : Longmans, Green, and Co. 1889.—An admirable description of macroscopic morbid anatomy, doing for medicine what Paget's lectures have done for surgery. May be studied with advantage both before and after practical work is engaged in.

Lectures on Pathology. By the late HENRY GAWEN SUTTON, M.B., F.R.C.P. Edited by MAURICE EDEN PAUL, M.D. ; and revised by SAMUEL WILKS, M.D., LL.D., F.R.S. London : J. & A. Churchill. 1891.—An admirable, philosophical, and original work on medical pathology, especially useful for senior and qualified students of medicine.

BACTERIOLOGY.

The following works will be found useful to students either for examination purposes or for special study :—

Ptomaines, Leucomaines, Toxins, and Antitoxins. By Professor VICTOR C. VAUGHAN, Ph.D., M.D. ; and Associate Professor FREDERICK G. NOVY, Sc.D., M.D. Third edition. Revised and enlarged. Philadelphia : Lea Brothers and Co. 1896. Pp. 604. $3.—The best book in the language on bacterial products and poisons. Well up to date as regards methods.

Manual of Bacteriology. By ROBERT MUIR, M.A., M.D., F.R.C.P. Edin., and JAMES RITCHIE, M.A., M.D., B.Sc. Edinburgh and London : Young J. Pentland. 1897.—An exceedingly good text-book for the medical student. Methods, descriptions, and illustrations alike excellent. The principles of bacteriology are well set forth. A most useful list of literature is appended. Well up to date in all respects.

Elementary Practical Bacteriology, including Bacteriological Analysis and Chemistry. By A. A. KANTHACK, M.D., M.R.C.P., and J. H. DRYSDALE, M.B., M.R.C.P. London : Macmillan and Co. 1896. Pp. 180. Sixteen Woodcuts. Price 4*s*. 6*d*.—A guide to the elementary study of bacteriology. The work deals in turn with general and special methods of cultivation and examination of micro-organisms, with the more important species of bacteria, and then with bacteriological analysis and bacteriological chemistry.

Micro-organisms and Disease. An Introduction to the Study of Specific Micro-organisms. By E. KLEIN, M.D., F.R.S. Fourth edition. Revised. Pp. 595, with 20 Illustrations. Price 10*s*. 6*d*. London : Macmillan and Co., Ltd. 1896.—A standard text-book.

Practical Guide to the Demonstration of Bacteria in the Animal Tissues. By Dr. H. KÜHNE. Translated and edited by VINCENT DORMER HARRIS, M.D., F.R.C.P. London : Baillière, Tindall, and Cox. 1890. Pp. 53. Figs. 7. 2*s*. 6*d*.—A practical little handbook.

Applied Bacteriology. By T. H. PEARMAIN and C. G. MOOR. London : Baillière, Tindall, and Cox. 1897. Price 12*s*. 6*d*. net.—A lucid exposition of bacteriology, especially as it relates to the work of the medical officer of health and to the student preparing himself for such work.

Medical Microscopy. By FRANK J. WETHERED, M.D., F.R.C.P. London : H. K. Lewis. 1891. Pp. 250. 40 Illustrations. Price 9*s*.—A guide to the preparation of microscopical preparations and examination of sputum, urine, &c. Useful for advanced students and general practitioners.

Bacteriological Technology for Physicians. By Professor C. J. SALOMONSEN. Translated by WILLIAM TRELEASE. Pp. 162, with 72 Figures in the text. New York : William Wood and Co. 1890.—A most concise and accurate work on methods, well adapted to the use of the student, as the apparatus described as necessary is both simple and inexpensive.

Manual of Bacteriology for Practitioners and Students. With especial reference to Practical Methods. By Professor S. L. SCHENK. Translated by W. R. DAWSON, B.A., M.D. With an Appendix by the Translator. 100 Illustrations, partly coloured. London and New York : Longmans, Green, and Co. 1893.—A really good student's text-book.

Studies on Fermentation. By L. PASTEUR. Translation, with Notes, Index, and original Illustrations, by FRANK FAULKNER and D. CONSTABLE ROBB, B.A. London : Macmillan and Co. 1879. Pp. 418, with 12 Plates and 85 Figures in text.—An admirable work and one that should be read by every advanced student of bacteriology.

On Fermentation. By P. SCHÜTZENBERGER. Fourth edition. London : Kegan Paul, Trench, Trübner, and Co., Ltd. 1891. Pp. 331, with 28 Illustrations. Price 5*s*. (Vol. XX., International Scientific Series.)—A capital *résumé* of the subject for advanced students.

Bacteria and their Products. By GERMAN SIMS WOODHEAD, M.D. 1891. Pp. 459, with 20 Photo-micrographs. London : Walter Scott. Price 3*s*. 6*d*.—Gives a description of the more important micro-organisms and the diseases they produce and of fermentation ; also a short history of bacteriology ; includes an appendix dealing with bacteriological methods and with the classification and identification of micro-organisms. Is in every respect a first-class text-book, excellent in arrangement and clear and full in detail.

A Manual of Bacteriology. By GEORGE M. STERNBERG, M.D. New York : William Wood and Co. 1892.—A most complete and exhaustive work of 886 pages, of which over a hundred are devoted to bibliography. An encyclopædic, painstaking, and usually accurate *résumé* of the subject. Well illustrated with chromo-lithographic plates and 268 engravings. Too ponderous for the ordinary student, but very useful for the advanced worker.

Text-book of Bacteriology. By EDGAR M. CROOKSHANK, M.B. London : H. K. Lewis. 21*s*. net. Fourth edition, reconstructed, revised, and greatly enlarged.—A well-written and well-illustrated treatise on the subject. A good text-book, especially for those who have no opportunity of attending a practical course.

FORENSIC MEDICINE.

Manual of Medical Jurisprudence. By A. S. TAYLOR. Edited by T. STEVENSON, M.D. Crown 8vo. Twelfth edition. 1891. 56 Engravings. 14*s*. London : J. & A. Churchill.—An authoritative text-book.

Text-book of Forensic Medicine and Toxicology. By ARTHUR P. LUFF, M.D., B.Sc. Lond. Two vols. Pp. 416 and 360. 24*s*. With numerous Illustrations. London and New York : Longmans, Green, and Co.—This recently published work is one of the best on the subject.

Principles of Forensic Medicine. By W. A. GUY and DAVID FERRIER, M.D., F.R.S. Seventh edition just published. 16*s*.—The work has been practically rewritten under the direction of Professor W. R. SMITH, M.D., F.R.S. Edin. London : Henry Renshaw.

Forensic Medicine and Toxicology. By J. DIXON MANN, M.D., F.R.C.P., Professor of Medical Jurisprudence and Toxicology, Owens College, Manchester ; Examiner in Forensic Medicine, London University, and Victoria University, Manchester. 21*s*.

A System of Legal Medicine. By ALLAN MCLANE HAMILTON, M.D., Consulting Physician to the Insane Asylums of New York City, &c., and Mr. LAWRENCE GODKIN, of the New York Bar. Illustrated with 14 Coloured Plates and 161 Woodcuts and Half-tone Plate. Fully indexed by 3202 references. Royal 8vo. Two vols. Pp. 1400. 30*s*. per volume. Only sold in sets.

Poisons : their Effects and Detection. By ALEXANDER WYNTER BLYTH, M.R.C.S. Third edition Revised and Enlarged. 1895. 21*s*. London : Chas. Griffin and Co.—A well-known work, much in esteem with toxicologists, partly as a book of reference, but chiefly as an excellent guide to the detection of poisons. The recent edition treats of the cadaveric alkaloids or ptomaines, and contains also a separate chapter on the connexion existing between the arrangement of the constituent parts of an organic molecule and physiological action.

Digitized by Google

PUBLIC HEALTH.

Public Health Laboratory Work. By HENRY R. KENWOOD, M.B. Edin., D.P.H. Second edition. London: H. K. Lewis. Price 10*s.* 6*d.*—An excellent little book of reference for the laboratory bench. It is written for students preparing for the diploma of public health, and describes the processes of analysis of food, water, air, &c., with which he must have a practical acquaintance. It also includes an account by Professor Boyce of the methods employed in bacteriological research.

Manual of Public Health. By WYNTER BLYTH, M.R.C.S., L.S.A. London: Macmillan and Co.—An excellent manual dealing with general principles. It is fairly exhaustive and affords a good book of reference.

Water and Water-Supplies. By J. C. THRESH, D.Sc., M.D. London: The Rebman Publishing Company, Limited.—A valuable dissertation on the important subject of water-supply. Besides practical details of the finding of water and the construction of wells, it contains also admirable chapters on the quality of water and the value of chemical and bacteriological analysis in enabling an opinion to be given upon it.

Public Health. Aids to Sanitary Science, for the Use of Candidates for Public Health Qualifications. By F. J. ALLAN, M.D., Dipl. Public. Health Camb., Assistant Professor of Hygiene, College of State Medicine. Price 4*s.* 6*d.* cloth. London: Baillière, Tindall, and Cox

The Elements of Vital Statistics. By ARTHUR NEWSHOLME, M.D. London: Swan Sonnenschein and Co.—A good text-book on vital statistics.

Hygiene and Public Health. By B. ARTHUR WHITELEGGE, M.D., B.Sc. London: Cassell and Co.—This is an admirable text-book in every way. It is well fitted for the student of public health, and it possesses the additional advantage that it can be carried in the pocket.

A Treatise on Hygiene and Public Health. Three vols. Edited by STEPHENSON and MURPHY. London: J. & A. Churchill.—This is quite the standard work at the present time. Vol. III. treats solely of sanitary law.

Knight's Annotated Model By-laws. London: Knight and Co.—This volume is almost essential for the student of public health.

Micro-organisms and Disease. By E. KLEIN, M.D., F.R.S. London: Macmillan and Co. New edition. 1896.—A capital introduction to the study of micro-organisms.

Vaccination Vindicated. By JOHN C. MCVAIL, M.D., D.P.H. London: Cassell and Co.—This is an answer to the leading anti-vaccinationists, and every student of public health should be familiar with it.

MEDICAL ELECTRICITY.

Medical Electricity: a Practical Handbook for Students and Practitioners. By H. LEWIS JONES, M.A., M.D., F.R.C.P. Second edition. With Illustrations, crown 8vo, 10*s* 6*d.* Pp. 454. 101 Figures in text. London: H. K. Lewis.—This is the best work on the subject in a small compass with which we are acquainted. Of course, it does not pretend to go as fully into the subject as the treatises of Von Ziemssen and Beard and Rockwell; but as a thoroughly practical guide to electrical diagnosis, the choice, preservation, and use of electrical apparatus for medical purposes, and the methods of application, it is unequalled. The illustrations, reproduced from photographs of patients with paralysis of particular muscles or groups of muscles, are a most useful feature of the work.

MISCELLANEOUS.

The following works will prove of service:—

Diseases and Injuries of the Teeth, including Pathology and Treatment: a Manual of Practical Dentistry for Students and Practitioners. By MORTON SMALE, M.R.C.S., L.S.A., L.D.S., Dental Surgeon to St. Mary's Hospital; and J. F. COLYER, L.R.C.P., M.R.C.S., L.D.S., Assistant Dental Surgeon to Charing-cross Hospital, &c. With 334 Illustrations. Large crown 8vo, 15*s*

The Anatomy of the Nasal Cavity and its Accessory Sinuses. By Dr. A. ONODI, Lecturer on Rhino-Laryngology in the University of Budapest. An atlas for practitioners and students, translated by ST. CLAIR THOMSON, M.D. Lond., F.R.C.S. Eng., M.R.C.P. Lond. Plates, small 4to, 6*s.* net. London: H. K. Lewis.

The Student's Guide to Diseases of the Chest, including the Principal Affections of the Pleuræ, Lungs, Pericardium, Heart, and Aorta. By VINCENT D. HARRIS, M.D., F.R.C.P., Physician to the Victoria Park Hospital for Diseases of the Chest. With 55 Engravings. Pp. 419. Fcap. 8vo, 7*s.* 6*d.* London: J. & A. Churchill.

Text-book of Diseases of the Ear and Adjacent Organs. By Professor POLITZER, of Vienna. Translated from the third German edition by OSCAR DODD, M.D., and edited by Sir WM. DALBY, B.A., M.B., F.R.C.S. Profusely illustrated. Price 21*s.* Baillière, Tindall, and Cox.—A reliable book, and contains all that is known on the subject.

Diseases of the Ear. Including the Anatomy and Physiology of the Organ, together with the treatment of the affections of the Nose and Pharynx which conduce to Aural Disease (a Treatise). By T. MARK HOVELL, F.R.C.S.E., M.R.C.S., Aural Surgeon to the London Hospital and Lecturer on Diseases of the Throat in the College, &c. 8vo, with 122 Engravings. 18*s.* 1894. London: J. & A. Churchill.

A System of Dental Surgery. By Sir JOHN TOMES, F.R.S., and C. S. TOMES, M.A., F.R.S. Third edition, crown 8vo. With 289 Engravings. 16*s.* 1897. London: J. & A. Churchill.

Dental Anatomy, Human and Comparative. A Manual. By CHARLES S. TOMES, M.A., F.R.S. Fourth edition. Crown 8vo, with 235 Engravings. 12*s.* 6*d.* 1894. London: J. & A. Churchill.

Manual of Botany. Vol. I., Morphology and Anatomy. By J. REYNOLDS GREEN, Sc.D., M.A., F.R.S., Professor of Botany to the Pharmaceutical Society. Crown 8vo, with about 778 Engravings. 7*s.* 6*d.* 1897 Vol. II., Classification and Physiology. 415 Engravings. 10*s.* London: J. & A. Churchill.

Dictionary of Medicine, Biology, and Allied Sciences. By G. M. GOULD, A.M., M.D. Price 40*s.* Baillière, Tindall, and Cox.—This is the best dictionary of medicine terms we have seen. It should find a place in the library of every medical man.

Outlines of Zoology. By THOMSON J. ARTHUR, M.A. Second edition, revised and enlarged, with 266 Illustrations in the text. Price 15*s.* Edinburgh: Young J. Pentland.

POST-GRADUATE INSTRUCTION ABROAD.

MEDICAL study is only nominally complete when a licence to practise is obtained, and all qualified men will acknowledge the importance of keeping themselves well informed in the various improvements in diagnosis and practice which are from time to time introduced. The opportunities afforded by post-graduate courses in this country are periodically referred to in the columns of THE LANCET; and with the object of treating the subject as fully as possible a short series of articles is now published, showing what is being done in this direction at the great continental schools. In this connexion it is not necessary to remind our readers that Vienna, for instance, has for many years been a favourite place of study for medical men desirous of completing their education after having gained their diplomas, and the institution of special courses there, to be carried on in the vacation months, will be a further inducement to resort to this famous centre of medical learning.

FRANCE.

There is not in France any special institution corresponding exactly to the post-graduate schools of some other countries. Students who wish their medical education to be more comprehensive than that which is required for obtaining a diploma usually undertake the additional study before the presenting of their thesis, because they may present their thesis whenever it suits them best, and they usually wait until their class-work is over and they are about to enter on practice. In Paris there are numerous advanced courses of instruction in subjects which are not required at the qualifying examinations, and they are attended by the above-mentioned section of students as well as by foreign medical men, already qualified to practise in their respective countries, who come to Paris in great numbers every year. Such courses

Digitized by Google

will be found at the Faculty of Medicine, at the College of France, at the Faculty of Sciences, at the Pasteur Institute, at the Museum of Natural History, in the free lectures delivered at the École Pratique of the Faculty, and in the polyclinics of individual surgeons. At the Faculty of Medicine a private course of bacteriology is given in a laboratory of the École Pratique; it is not official, because there is not as yet a chair of bacteriology at the Faculty; it is conducted by M. Chantemesse, and consists of demonstrations, the use of the microscope, and the making of cultivations, including the study of the most important micro-organisms. Many of the official lectures delivered at the Faculty are, either from the nature of the subjects or from the advanced style in which they are treated, more adapted to medical graduates than to students; lectures to students are the special province of the assistant professors (*agrégés*), who confine themselves to instruction of the usually accepted kind. It may almost be said that medical education in Paris is embodied in the lectures delivered by the assistant professors, and that the lectures of the professors form a kind of school of a higher grade, free from anxiety about examinations and not occupied with matters of common knowledge. All the lectures of the professors and the assistant professors are public, and fees are charged for attendance. The professors' lectures, which are most largely attended by foreigners, are those on general pathology (Professor Bouchard), on Experimental and Comparative Pathology (Professor Chantemesse), on Forensic Medicine (Professor Brouardel), on Hygiene (Professor Proust), on Pathological Anatomy (Professor Cornil), &c. In addition there are at the hospitals four extensive courses on Clinical Medicine, four on Clinical Surgery, four on Nervous Diseases, two on Clinical Obstetrics, one on Syphilis, one on Affections of the Urinary Passages, one on Ophthalmology, and one on Diseases of Children, each of them constituting a small school in which the same organisation is repeated on a reduced scale, the professor discoursing on unusual and difficult cases to advanced students and practitioners who wish to increase their stock of knowledge, whilst the assistants and the *chefs de clinique* deliver more elementary expositions to the students. Moreover, in the majority of the hospitals the physicians and surgeons have of their own accord arranged for an analogous organisation, independent of the Faculty, and some of these courses are very popular on account of the excellence of individual teachers. Under this head may be mentioned the course on Gynæcology given by Dr. Pozzi at the Hôpital Broca, that given by Dr. Doléris at La Pitié, that on Diseases of the Heart and Vessels given by Dr. Huchard at the Hôpital Necker, that on Obstetrics given by Dr. Budin at the Maternité, and those on Surgery given by Dr. Terrier and Dr. Lucas-Championnière, that on Diseases of the Stomach given by Dr. Debove, &c. This constitutes the clinical instruction obtainable in the hospitals; it is free, but is given by physicians and surgeons attached to the hospitals.

At the College of France there are numerous courses in the higher branches of various subjects, some of which have a bearing on medical questions—such, for instance, as that on Experimental Medicine (Professor d'Arsonval), that on the Natural History of Organised Bodies (delivered by Professor François Franck and developed into a course on Physiology), and that on General Anatomy (Professor Rouvier). This last-mentioned chair is in reality an advanced School of Histology; the lectures of the professor are public and free; there is also a special course lasting two months.

At the Museum of Natural History will be found courses on Comparative Anatomy (Professor Filhol), on General Physiology (Professor Gréhant), on Comparative Pathology (Professor Chauveau), and on Anthropology (Professor Hamy). All these lectures are delivered three times a week; they are open to the public and are free.

At the Faculty of Sciences there are lectures on Physiology (Professor Dastre), on Biological Chemistry (Professor Duclaux), and on the Evolution of Organised Beings (Professor Giard).

To all these chairs there are attached spacious laboratories in connexion with an organisation which unites them all under the name of the École des Hautes Études. Admission to these laboratories is always granted on application being made to the professor; in general there is no fee for admission, but any outlay required for the work that is undertaken has to be paid for. The workers are under the control of the professor, whether they undertake original investigation or merely seek to increase their knowledge of recognised subjects; in almost all the laboratories lectures are delivered by the assistants.

At the School of Anthropology there are free public lectures on Prehistoric Anthropology, Medical Geography, Ethnography, Ethnology, Biological Anthropology, Zoological Anthropology, Physiological Anthropology, Sociology, and Comparative Ethnography.

The Pasteur Institute has an admirably organised school of Microbiology and numerous laboratories arranged in five services, with accommodation for fifty persons. In order to be admitted to this school it is necessary to send an application to the institute, together with a description of the investigations or the work contemplated. A person so admitted can remain at the institute for an indefinite time provided that his work is continuous. For working in the laboratories there is a fixed charge of 50 francs (£2) a month, which, however, is remitted in the case of a certain number of students selected by the institute. The five laboratory services above-mentioned are as follows: (1) Rabies (M. Grancher, M. Charrin, and M. Chantemesse); (2) general microbiology (M. Duclaux); (3) technical microbiology (M. Roux), together with laboratory for diphtheria (M. Martin); (4) microbiology applied to hygiene, including vaccins (M. Chamberland); and (5) morphological and comparative microbiology (M. Metchnikoff). The department of technical microbiology presided over by M. Roux is devoted to teaching as well as to original investigation. The course of instruction lasts six weeks, and admission to it is obtained by merely entering one's name and paying a fee of 50 francs (£2). As the places assigned to workers are at present not very numerous it is necessary to enter one's name two years in advance.

Finally, there are in Paris numerous private hospitals and polyclinics which are well attended by both students and practitioners. At some there are lectures open to all-comers and free. In others the medical men who attend accompany the physician or surgeon on his visit, and clinical instruction is given on the cases which happen to be under treatment; such is the case in the celebrated ophthalmological clinics (Galezowski, de Wecker, Landolt, &c.), as well as in those of laryngology and gynæcology. The laryngological clinic of Dr. Castex has recently been incorporated with the School of Medicine, and a fee is charged for instruction. With this exception it is in all cases sufficient to apply to the physician or surgeon for permission to attend his clinic, and the request is immediately granted.

GERMANY.

Post-graduate lectures and demonstrations are given in most of the universities of Germany. As a rule, their duration is from three to four weeks, the university vacation being the usual period. They are delivered partly by the ordinary professors and partly by *privat-docents* or lecturers. These lectures and demonstrations are not included in the official course of university instruction, they are private undertakings; but those who attend them are none the less freely admitted to the university laboratories and hospitals. Medical men wishing to join these courses have no formalities to comply with beyond entering their names and paying the fees for the lectures or the practical work which they happen to prefer. In the event of their intending to study in Berlin they should apply to Mr. Anders, Registrar of the Association for Post-graduate Study, Langenbeck House, N.W. Ziegelstrasse 8. Lists of the lectures may be obtained from this gentleman, and may also be seen in the advertisement columns of the leading German medical journals.

AUSTRIA.

Courses of lectures, the attendance on which is limited to medical men in practice, are delivered in Vienna, but not in any other Austrian University. They have been introduced on the initiative of Professor Wagner, who has for a year been Dean of the Vienna Medical Faculty, and has appointed two months (August and September) during which they are delivered in two series by the most eminent *privat-docents* and assistants of the faculty. Each course lasts four weeks, and the fees vary from twenty gulden (£1 17*s.*) to fifty gulden (£4 13*s.*), according to the subject. The first series began on Aug. 2nd and comprised the following courses: Pathological Anatomy (Dr. Albrecht and Dr. Stoerk), Bacteriology (Dr. Ghon), Experimental Pathology (Dr. Biedl), Pharmacology (Dr. Hockauf), Internal Medicine (Dr. Hammerschlag, Dr. Czinner, and Dr. Türk), Neuro-pathology (Dr. Redlich), Diseases of Children

Digitized by Google

(Dr. Franz), Ophthalmology (Dr. Topolanski, Dr. Hanke, Dr. Gruber, and Dr. Königstein), Laryngology (Dr. Grossmann, Dr. Rethi, Dr. Ebstein, and Dr. Koschier). Diseases of the Ear (Dr. Bing and Dr. Kaufmann), Dermatology and Syphilis (Dr. Rille and Dr. Spiegler), Obstetrics and Gynæcology (Dr. Wertheim, Dr. Woyer, Dr. Hink, Dr. Ludwig, Dr. Knauer, and Dr. Savor). The second series will begin on Sept. 1st and will include the following courses:—Anatomy (Dr. Tandler), Pathological Anatomy (Dr. Kolisko and Dr. Albrecht), Bacteriology (Dr. Ghon), Experimental Pathology (Dr. Biedl), Forensic Medicine (Dr. Haberda), Internal Medicine (Dr. Pal, Dr. Schlesinger, Dr. Eisenschitz, and Dr. Sternberg), Surgery (Dr. Fraenkel), Dr. Schnitzler, and Dr. Friedländer), Ophthalmology (Dr. Bernheimer, Dr. Königstein, Dr. Sachs, and Dr. Wintersteiner), Diseases of the Ear (Dr. Bing, Dr. Pollak, Dr. Alt, and Dr. Kaufmann), Dermatology and Syphilis (Dr. Rille, Dr. Spiegler, and Dr. Zeissl), Obstetrics and Gynæcology (Dr. Lott, Dr. Braun, Dr. Herzfeld, Dr. Wertheim, Dr. Neumann, Dr. Woyer, Dr. Ludwig, Dr. Knauer, and Dr. Savor). These courses are likely to be preferred by medical practitioners to those delivered during the session from October to July, as they are not attended by students.

ITALY.

In many Italian medical schools special courses of instruction, clinical and theoretical, are now given to men who are already engaged in practice. Those who attend are mostly either on the one hand dispensary practitioners or divisional surgeons (medici condotti) or, on the other hand, graduates who take up special courses of study (particularly laboratory work) in order to become eligible for public health appointments under Government. For instance, at the University of Pavia a special series of lectures and demonstrations in hygiene has just been brought to a conclusion. The course was organised by Dr. Giuseppe Sormani, professor of the subject in the University, and was attended by graduates from all parts of Italy, attracted not only by the well-known expository power of the professor, but also by the preferential claim to sanitary posts conferred on all who have passed the examinations instituted by the Pavian school. Again, at Genoa, the post-graduate session of Dr. Maragliano, Professor of Clinical Medicine in that school, attracts an increasing attendance from other provinces besides those of the Alta Italia. In this course instruction is given in the refinements of sero-therapy, particularly as applied to pulmonary tuberculosis.

HUNGARY.

Foreign medical men who do not desire to obtain Hungarian qualifications, but merely to increase their knowledge by post-graduate study, will find no difficulty in pursuing their objects. They are allowed to enrol themselves among the "ausserordentliche Hörer" (students in special subjects) at a comparatively low fee, and are given every facility for practical study; vivisection, for instance, is amply provided for. All the lectures are delivered in the Hungarian language, but all the professors and teachers speak German, and some of them speak French and English as well. The cost of living in Budapest is nearly the same as in Vienna; the journey between the two towns takes five hours by railway.

THE INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND.—At the recent July examinations the following were the names of those candidates who passed the Practical Examination for the Associateship: James Bruce, B.Sc. Lond., Harry Burrows, Robert George Grimwood, Robert Ferris Lyle, Robert Curling Styles, Assoc. R.C. Sc. Lond., and Arthur Lee White. The following passed the Intermediate Examination: William Bowen, Harry Thornton Calvert, B.Sc. Vict., Alexander Hugh Dewar, Albert Lucas Entwistle, and Bertram William John Warren. In the Final Examination for the Associateship the successful candidates were as follows:—Reginald Arthur Berry, James Hembrough, Assoc. R.C.Sc. Lond., Robert Dexter Littlefield, Charles Alfred West, Assoc. R C.Sc. Lond., Frederick John Bolt (Fellowship), John Alfred Foster, Albert Edward Parkes, James Darnell Granger, Ph D. Berlin (Fellowship), Gilbert Thomas Morgan, B.Sc. Lond., John Henry Sugden, B.Sc. Vict., and Frederic William Richardson (Fellowship).

SESSION 1897–98.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

Registration of Medical Students.—The following are the General Medical Council's Regulations in reference to the registration of students in medicine:—

Every medical student shall be registered in the manner prescribed by the General Medical Council. No medical student shall be registered until he has passed a preliminary examination as required by the General Medical Council, and has produced evidence that he has commenced medical study. The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration. The registration of medical students shall be placed under the charge of the branch registrars. Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing; and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has commenced medical study. The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration. Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals, in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students. Applications for special exceptions are dealt with by the Students' Registration Committee, which reports all such cases to the Council.

The Preliminary Examination in General Education, required to be passed previously to registration as a Medical Student, shall be as follows:—

"1. English language, including grammar and composition. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Mathematics, comprising (*a*) arithmetic, (*b*) algebra, as far as simple equations, inclusive; (*c*) geometry, the subject matter of Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects: (*a*) Greek, (*b*) French, (*c*) German, (*d*) Italian, (*e*) any other modern language, (*f*) logic."

The Council will not in future accept any certificate of pass in Preliminary Examination in General Education unless the whole of the subjects included in the Preliminary Examination required by the Council for Registration of Students of Medicine have been *passed at the same time*.

Professional Education.—For those who commenced study after Jan. 1st, 1892, the course of professional study after registration shall occupy at least five years. The Final examination in Medicine, Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study.

H. E. Allen, LL.B., Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W.—James Robertson, Registrar of the Branch Council for Scotland, 48, George-square, Edinburgh.—S. W. Wilson, Registrar of the Branch Council for Ireland, 35, Dawson-street, Dublin.

The following is a list of Examining Bodies whose examinations in general education are recognised by the General Medical Council as qualifying for registration as a medical or dental student the applicant producing satisfactory evidence that he has passed them:—

I.—UNIVERSITIES IN THE UNITED KINGDOM.

University of Oxford.—Junior Local Examinations. Senior Local Examinations. Responsions. Moderations. Examination for a degree in Arts.

University of Cambridge.—Junior Local Examinations. Senior Local Examinations. Higher Local Examinations. Previous Examination. General Examination. Examination for a degree in Arts.

University of Durham.—Examination for Certificate of Proficiency. Preliminary Examination in Arts for Graduation in Medicine and Science. Examination for a degree in Arts.

University of London.—Matriculation Examination. Examination for a degree in Arts or Science.

Victoria University.—Preliminary Examination. Entrance

Digitized by Google

Examination in Arts. Final Examination for a degree in Arts or Science.

University of Wales.—Matriculation Examination. Final Examination for a degree in Arts.

University of Edinburgh.—Local Examinations (Senior and Junior). Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Examination for a degree in Arts or Science.

University of Aberdeen.—Local Examinations (Senior and Junior). Preliminary Examination for Graduation in Arts or Science or Medicine or Surgery. Examination for a degree in Arts or Science.

University of Glasgow. — Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Examination for a degree in Arts or Science.

University of St. Andrews.—Preliminary Examination for Graduation in Arts or Science or Medicine and Surgery. Examination for a degree in Arts or Science. Final Examination for the diploma of L.L.A.

University of Dublin. — Public Entrance Examination. Examination for the first, second, third, or fourth year in Arts. Examination for a degree in Arts.

Royal University of Ireland.—Matriculation Examination. Examination for a degree in Arts or Science.

Oxford and Cambridge Schools Examination Board.—Lower certificate (to include all the required subjects at one time). Higher certificate (to include the required subjects).

II.—MEDICAL LICENSING BODIES.

Royal Colleges of Physicians and Surgeons in Ireland.—Preliminary Examination (Certificate to include all the required subjects at one time).[1]

III.—EDUCATIONAL BODIES OTHER THAN UNIVERSITIES.

College of Preceptors.—Examination for a First Class Certificate or Second Class Certificate of First or Second Division. Preliminary Examination for Medical Students.

Intermediate Education Board of Ireland.—Junior Grade Examination; Middle Grade Examination; Senior Grade Examination (Certificate in each case to include all the subjects required).

Educational Institute of Scotland. — Preliminary Medical Examination.

Scotch Education Department. — Leaving Certificates in Lower and Higher Grades and in Honours.

IV. — INDIAN, COLONIAL, AND FOREIGN UNIVERSITIES AND COLLEGES.

The Certificates from Indian, Colonial, and Foreign Universities and Colleges must contain evidence "that the Examination has been conducted by or under the authority of the Body granting it, includes all the subjects required by the General Medical Council, and states that all the subjects of Examination have been passed in at one time; and copies of the form of the required Certificate will be supplied by the Registrar of the Council for the purpose. In the case of Natives of India or other Oriental countries, whose vernacular is other than English, an Examination in a Classic Oriental Language may be accepted instead of an Examination in Latin."

REGULATIONS OF THE MEDICAL EXAMINING BODIES IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD.

THERE are two degrees in Medicine, B.M. and D.M., and two degrees in Surgery, B.Ch. and M.Ch.

The B.M. and B.Ch. degrees are granted to those members of the University who have passed the Second Examination. Graduates in Arts (B.A. or M.A.) are alone eligible for these two degrees. In order to obtain the degrees of B.M. and B.Ch. the following examinations must be passed:—1. Preliminary subjects: Mechanics and Physics, Chemistry, Animal Morphology and Botany. 2. Professional. (*a*) First Examination: Subjects — Organic Chemistry, unless the candidate has obtained a first or second class in Chemistry in the Natural Science School; Human Physiology unless he has obtained a first or second class in Animal Physiology in the Natural Science School; Human Anatomy, and Materia Medica with Pharmacy. (*b*) Second Examination: Subjects — Medicine, Surgery, Midwifery, Pathology, Forensic Medicine with Hygiene. The approximate dates of the examinations are as follows:—Preliminaries—Mechanics, Physics and Chemistry, December and June; Animal Morphology and Botany, December and March; Professional (First and Second B.M.), June and December.

The degree of D.M. is granted to Bachelors of Medicine of the University—(1) who took the degree of B.M. previously to the end of Trinity Term, 1886, provided they have spent three years in the practice of Medicine after taking that degree, and have composed a dissertation on some medical subject approved by the Regius Professor of Medicine, before whom it must be read in public; (2) who took the degree of B.M. subsequently to the end of Trinity Term, 1886, provided they have entered their thirty-ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of B.M. whose subject is dealt with. A book published within two years of the candidate's application for the degree may be substituted for a dissertation. The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed an examination in Surgery, Surgical Anatomy, and Surgical Operations. This examination is held annually, in June, at the end of the Second B.M. Examination.

The First Examination for the degrees of B.M. and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed. The subjects of this examination may be presented separately or in any combination or in any order, provided Anatomy and Physiology be passed together.

The Second Examination may be passed after the completion of the first. Before admission to the Second Examination candidates must present Certificates of instruction in Infectious and Mental Diseases, and of attendance on Labours, and of proficiency in the practice of Vaccination.

Scholarships, &c.—Scholarships in some branch of Natural Science (Chemistry, Physics, Biology) of the average value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as Exhibitions of a less annual value, are awarded after competitive examination every year by some of the Colleges. Notices of vacancy, &c., are published in the *University Gazette*. In February there is competed for annually, by those who, having obtained a first-class in any school (Moderations or final), or a Scholarship or Prize open to general competition in the University, have passed all the examinations for the degree of B.A., one Radcliffe Travelling Fellowship. It is tenable for three years, and is of the annual value of £200. The examination is partly scientific, partly medical. The holder must travel abroad for the purpose of medical study. A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing for an original research in some Biological subject including Physiology or Pathology

More detailed information may be obtained from the University Calendar; from the Examination Statutes, 1894, which contain the official schedules of the several subjects of examination in both Arts and Medicine; from the Student's Handbook to the University; from the Regius Professor of Medicine; and from the Professors in the several departments of science.

The Lecturers for the various subjects are as follows:—Regius Professor of Medicine: J. S. Burdon Sanderson, D.M. Pathological Histology and Practical Bacteriology: The Lecturer on Pathology, J. Ritchie, D.M. Edin. Professor of Human Anatomy: A. Thomson, M.A. Waynflete Professor of Physiology: F. Gotch, M.A.; Advanced Course: the Lecturer on Physiology, J. S. Haldane, M.A. Practical Physiology and Histology: G. Mann, D.M. Edin. Lichfield Lecturer in Clinical Medicine: G. J. Wilson, M.A., D.M.Dub. Lichfield Lecturer in Clinical Surgery: W. L. Morgan, M.A. Organic Chemistry in Relation to Medicine, &c., followed by Practical Work: Aldrichian Demonstrator, W. W. Fisher, M.A., and J. E. Marsh, M.A. Lecturer in Materia Medica, J. E. Marsh, M.A. Linacre Professor of Comparative

[1] The Council has recommended that this examination be discontinued.

Digitized by Google

Anatomy, E. Ray Lankester, M.A. Elementary Animal Morphology (Practical): the Aldrichian Demonstrator, W. B. Benham, M.A., and assistants. Sherardian Professor of Botany: S. H. Vines, M.A; Wayndete Professor of Chemistry: W. Odling, M.A. Inorganic Chemistry: A. G. Vernon Harcourt, M.A. Laboratory Instruction: W. W. Fisher, M.A.; J. Watts, M.A.; V. H. Veley, M.A.; and J. E. Marsh, M.A. Professor of Experimental Philosophy: R. B. Clifton, M.A. Instruction in Practical Physics: Professor Clifton, M.A.; J. Walker, M.A.; W. F. S. Churchill, B.A.; and J. C. Alsop, B.A. Elementary Heat and Light: R. E. Baynes, M.A. Elementary Mechanics; F. J. Smith, M.A.

UNIVERSITY OF CAMBRIDGE.

The student must enter at one of the Colleges, or as a non-collegiate student, and keep nine terms by residence in the University. He must pass the Previous Examination in Classics, Mathematics, &c., which may, and should if possible, be done immediately on coming into residence in October, or, what is better, obtain exemption through the Oxford and Cambridge Schools Examination Board or the Cambridge Senior Local Examinations, before commencing residence. He may then devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c. Or he may, as nearly all students now do, proceed to take a degree in Arts, either continuing mathematical and classical study and passing the ordinary examinations for B.A., or going out in one of the Honour Triposes. The Natural Sciences Tripos is the most appropriate, as some of the subjects are practically the same as those for the first and second M.B. examinations.

For the degree of *Bachelor of Medicine (M.B.)* five years of medical study are required. This time may be spent in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed, say, the examination for the Natural Sciences Tripos and the first and second examinations for M.B. Cambridge being now a complete School of Medicine, all the requisite lectures and hospital practice may be attended here, and many students remain to attend lectures and hospital practice until they have passed the first part of the third examination for M.B. The supply of subjects for Dissection, Practical Surgery, &c., is abundant.

There are three examinations for M.B. The *first* in Chemistry and other branches of Physics, and in Elementary Biology. These parts may be taken together or separately. The *second* in Human Anatomy and Physiology and in Pharmaceutical Chemistry. These may be taken together or separately. The *third* may also be taken in two parts—viz., (1) Principles and Practice of Surgery (with Operative and Clinical Surgery) and Midwifery and Diseases of Women; and (2) Pathology, Principles and Practice of Medicine, including Pharmacology and Therapeutics, Elements of Hygiene, Medical Jurisprudence and Mental Diseases. The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting-room, and in the laboratories. An Act has then to be kept in the Public Schools, by the candidate reading an original dissertation composed by himself on some subject approved by the Regius Professor of Physic.

As Operative and Clinical Surgery now form parts of the third M.B. examination candidates who have passed both parts of that examination are admitted to the degree of *Bachelor of Surgery (B.C.)* without separate examination, and without keeping an Act.

The degree of *Doctor in Medicine* may be taken three years after that of M.B., or four years after that of M.A. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools, with *vivâ-voce* examination; and an extempore Essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine.

For the degree of *Master in Surgery (M.C.)* the candidate must have passed all the examinations for B.C. He is required either (1) to pass an examination in Surgical Anatomy and Surgical Operations, Pathology and the Principles and Practice of Surgery, and to write an extempore Essay on a Surgical Subject; or (2) to submit to the Medical Board original contributions to the advancement of the Science or Art of Surgery. Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B.C.

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, and Pharmaceutical Chemistry may be obtained upon sending a stamped directed envelope to the Registrary, Cambridge. Full information is contained in the *Cambridge University Calendar*.

UNIVERSITY OF LONDON.

The *Matriculation Examination*.—Candidates for any degree in this University must have passed the Matriculation Examination. No exemption either from Matriculation or from subsequent examinations is allowed on account of degrees obtained at other Universities or of examinations of other examining bodies that may have been passed. The examinations take place twice in each year—on the second Monday in January and the second Monday in June; and may be held not only at the University of London, but also, under special arrangement, in other parts of the United Kingdom or in the colonies. Every candidate must, not less than five weeks before the commencement of the examination, apply to the Registrar for a form of entry, which must be returned not less than four weeks before the commencement of the examination, accompanied by a certificate showing that the candidate has completed his sixteenth year, and by his fee for the examination. A certificate from the Registrar-General in London or from the superintendent registrar of the district, or a certified copy of the baptismal register, is required in every case in which it can possibly be obtained. In other cases a declaration of the candidate's age, made before a magistrate by his parent or guardian, or by the candidate, if of full age, will be accepted. As candidates cannot be admitted after the list is closed, any candidate who may not have received a form of entry within a week after applying for it should communicate immediately with the Registrar, stating the exact date of his application and the place where it was posted. Every candidate must pay a fee of £2, and if he withdraws his name, or fails to present himself at the examination, or fails to pass it, the fee shall not be returned to him, but he shall be allowed to enter for any subsequent matriculation examination upon payment at every such entry of an additional fee of £1, provided that he comply with the other regulations. Candidates must show a competent knowledge of: 1. Latin. 2. One of the following languages: Greek, French, German, Sanskrit, Arabic. (No credit will be given for more than one, and candidates desiring to be examined in the last two must give two months' notice to the Registrar.) 3. The English Language, English History, and Geography. 4. Mathematics (Elementary). 5. Mechanics (Elementary). 6. One of the following branches of science: Chemistry, Heat and Light, Magnetism and Electricity, Botany. (No credit will be given for more than one of these subjects. The examination in Botany is only held in the United Kingdom. Candidates in any one of the optional Branches of Science will find it an advantage to have obtained some elementary instruction in the practical use of apparatus.) A pass certificate signed by the Registrar is delivered to each successful candidate after the report of the examiners shall have been approved by the Senate. The first six candidates in the Honours Division, of not more than twenty years of age at the commencement of the examination, shall respectively receive an exhibition or a prize. Any candidate obtaining a place in the Honours Division at the matriculation examination in January shall be admissible to the intermediate examination either in Arts or in Science in the following July.

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations, and are carried on simultaneously with the examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any provincial centre must give notice upon their forms of entry to the Registrar of the University, who will then make all necessary arrangements. Besides the University fee, a fee usually varying from £1 to £2 is

Digitized by Google

charged by the local authorities, and must be paid *at the local centre* immediately before the commencement of the several examinations. The answers of the candidates at the provincial examinations are reviewed by the examiners at the same time as the answers of the candidates examined in London, and a list of the candidates who have passed at each provincial examination is published at the time fixed by the regulations at the place where such examination has been held.

The *Preliminary Scientific (M.B.) Examination.*—Professional studies pursued before the whole of this examination has been passed will not count towards the course required for the M.B. degree The examination takes place twice in each year, once for Pass and Honours, commencing on the third Monday in July, and once for Pass candidates, only, commencing on the third Monday in January. Every candidate must, not less than five weeks before the commencement of the examination, apply to the Registrar for a form of entry, which must be returned not less than four weeks before the commencement of the examination, accompanied by the candidate's fee of £5. The subjects of the Preliminary Scientific Examination are divided into two sections: (1) Chemistry and Physics, (2) General Biology. Chemistry includes a written examination in Inorganic Chemistry and a *viva voce* examination in Qualitative Analysis. Physics implies a knowledge of acoustics, heat, magnetism, electricity, and optics. General Biology comprises a knowledge of the elements of zoological (vertebrate or invertebrate), and botanical morphology, physiology, and embryology. Candidates shall be allowed to enter for the whole examination or for either section. Candidates who present themselves for the two sections together shall be credited with either section in which they may have passed, although they may have failed to pass in the other, but no such candidate shall be placed in the Honours List. Candidates must bear in mind that the standard of attainment for the Honours examination is much higher than that for the Pass examination; and they should therefore exercise due caution in making their choice, to which they will be required to adhere. A candidate who has entered for the Pass examination will not be allowed to take the Honours papers; and only under special circumstances will a candidate who has entered for Honours in any subject be transferred to the Pass examination in that subject. The fee of £5 covers the whole of the examination, whether taken altogether or in sections.

Provincial Examinations for the Preliminary Scientific (M.B.) Examination.—These examinations are held in July only at nearly the same places as those appointed for the June Provincial Matriculation examinations. The practical examinations in chemistry are conducted at the provincial centres, but all candidates must attend at the University for the practical examinations in Physics and Biology.

Bachelor of Medicine.—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation Examination in this University not less than five years previously. 2. To have passed the Preliminary Scientific (M.B.) Examination not less than four years previously. 3. To have been engaged in his professional studies during five years subsequent to matriculation and four years subsequent to passing the Preliminary Scientific Examination[2] at one or more of the medical institutions or schools recognised by this University, one year at least of the four being spent in one or more of the recognised institutions or schools in the United Kingdom. 4. To pass two examinations in Medicine.

Intermediate Examination.—The Intermediate Examination in Medicine takes place twice in each year—once for Pass and Honours commencing on the second Monday in July, and once for Pass candidates only, commencing on the third Monday in January. The subjects of the examination are Anatomy, Physiology and Histology, Organic Chemistry, Materia Medica, and Pharmaceutical Chemistry. The standard of attainment required for Honours is much higher than for a Pass. No candidate shall be admitted to this examination unless he have passed the Preliminary Scientific Examination at least two years previously, and have produced certificates to the following effect:—1. Of having completed his nineteenth year. 2. Of having, subsequently to having passed the Preliminary Scientific Examination, been a student during two years at one or more of the medical institutions or schools recognised by this University, and of having attended a course of lectures on each of three of the subjects in the following list: Descriptive and Surgical Anatomy, Physiology and Histology, Pathological Anatomy, Materia Medica and Pharmacy, General Pathology, General Therapeutics, Forensic Medicine, Hygiene, Obstetric Medicine and Diseases peculiar to Women and Infants, Surgery, Medicine. 3. Of having, subsequently to having passed the Preliminary Scientific Examination, dissected during two sessions. 4. Of having, subsequently to having passed the Preliminary Scientific Examination, attended a course of Practical Chemistry, comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry, in applying tests for discovering the adulteration of articles of the Materia Medica and the presence and nature of poisons, and in the examination of mineral waters, animal secretions, urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy and of having acquired a practical knowledge of the preparation of medicines. These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the Registrar at least four weeks before the commencement of the examination. Fee for this examination, £5

M.B. Examination.—The M B. Examination takes place twice in each year—once for Pass and Honours, commencing on the last Monday in October, and once for Pass candidates only, commencing on the first Monday in May. The subjects of the examination are General Pathology, General Therapeutics, Hygiene, Surgery, Medicine, Obstetric Medicine, and Forensic Medicine. No candidate will be admitted to this examination within twenty-one months of the time of his passing the Intermediate Examination unless he be a registered medical practitioner of not less than three years' standing, in which case he must produce a certificate of having gone through the required course of training at some time previously. Every candidate must produce certificates:—1. Of having passed the Intermediate Examination. 2. Of having attended a course of lectures on each of two of the subjects enumerated above in the regulations for that examination for which the candidate had not on that occasion presented certificates. 3. Of having conducted at least twenty labours. Certificates on this subject will be received from any legally qualified practitioner in Medicine. 4. Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery. 5. Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine, including Infectious Diseases and Lunacy. 6. Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate Examination in Medicine, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5. 7. Of having acquired proficiency in Vaccination. Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council. The fee for this examination is £5.

Bachelor of Surgery.—The examination for the degree of Bachelor of Surgery takes place once in each year, and commences on the Tuesday following the first Monday in December. Candidates must produce certificates to the following effect:—1. Of having passed the examination for the degree of Bachelor of Medicine in this University. 2. Of having attended a course of instruction in Operative Surgery and of having operated on the dead subject. The subjects of the examination are Surgery and Pathology and Surgical Anatomy. Fee £5.

Master in Surgery.—The examination for the degree of Master in Surgery takes place once in each year, and commences on the first Monday in December. Candidates must produce certificates to the following effect: 1. Of having taken the degree of Bachelor of Surgery in this University. 2. Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University:

[2] Candidates who passed the Matriculation Examination in January, 1885, or previously, will be allowed to date the commencement of their professional studies, as heretofore, from that examination.

Digitized by Google

(*a*) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University; or (*b*) to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession; or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University. One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B.S. Examination have been placed in the first division. 3. Of moral character, signed by two persons of respectability. The examination is conducted by means of printed papers and *viva-voce* interrogation, and the subjects are Mental Physiology (especially in its relations to mental disorder) and Surgery. Any candidate for the degree of M.S. may transmit to the Registrar, not later than Oct. 1st, a printed Dissertation, Thesis, or Commentary, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Surgical Science; and if the Thesis be approved by the examiners the candidate will be exempt from the written examination in Surgery. The fee is £5.

Doctor of Medicine.—The examination for this degree takes place once in each year, and commences on the first Monday in December. Candidates may present themselves for examination either in Medicine or State Medicine. Those presenting themselves for the M.D. Examination in Medicine must produce certificates to the following effect:—1. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University: (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; (*b*) or to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of their profession; (*c*) or of having been engaged during five years in the practice of their profession, either before or after taking the degree of Bachelor of Medicine in this University. 2. Of moral character, signed by two persons of respectability. One year of attendance on Clinical or Practical Medicine or two years of practice will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the First Division. Candidates presenting themselves for the M.D. Examination in State Medicine must produce certificates to the following effect:—1. Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this university: (*a*) to State Medicine during two years, including six months' practical instruction in a laboratory and six months' out-door sanitary work; (*b*) or to State Medicine during one year, and of having held for a period of two years the position of medical officer of health in any sanitary district; (*c*) or of having held for a period of three years the position of medical officer of health in any sanitary district. 2. Of moral character. One year of attendance on State Medicine or one year of holding the position of medical officer of health will be dispensed with in the case of those candidates who at the M.B. Examination have been placed in the First Division. The examination is conducted by means of printed papers and *viva-voce* interrogation, and the subjects are Medicine (or State Medicine) and Mental Physiology. Any candidate for the degree of M.D. may transmit to the Registrar, not later than Oct. 1st, a printed Thesis, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Medical Science; and if the Thesis be approved by the examiners the candidate will be exempt from the written examination in Medicine (or State Medicine). Fee for this degree, £5.

UNIVERSITY OF DURHAM.

One Diploma and six degrees are conferred—viz., the Diploma in Public Health and the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene. These degrees are open both to Men and Women.

For the degree of *Bachelor in Medicine* (*M.B.*) there are four professional examinations.

The subjects of the First Examination are—Elementary Anatomy and Elementary Biology, Chemistry, and Physics.

The subjects for the Second Examination are—Anatomy, Physiology, Materia Medica, Therapeutics, Pharmacology, Pharmacy.

The subjects for the Third Examination are—Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.

The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Midwifery and Diseases of Women and Children.

N.B.—It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle-upon-Tyne.[2] Candidates for the First Examination who have passed the First Examination of the Conjoint Board in England will be exempt from the First Examination of the University, except in the subjects of Elementary Anatomy, Chemistry, and Physics, and candidates who hold a qualification from a recognised Licensing Body in the United Kingdom will be exempt from the First Examination of the University, except in the subjects of Chemistry and Physics. Candidates who have passed the First and Second Examinations of the University will be exempt from First and Second Examinations of the Conjoint Board.

For the degree of *Bachelor in Surgery* (*B.S.*) every candidate must have passed the examination for the degree of Bachelor in Medicine of the University of Durham, and must have attended one course of lectures on Operative Surgery and one course on Regional Anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of *Master in Surgery* (*M.S.*) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor in Surgery of the University of Durham, and must have been engaged for at least two years subsequent to the date of acquirement of the degree of Bachelor in Surgery, in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice.

The subjects of examination are:—Principles and Practice of Surgery, Surgical Pathology, Surgical Anatomy, Surgical Operations, Clinical Surgery.

For the degree of *Doctor in Medicine* (*M.D.*) candidates must be not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor in Medicine of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Medicine, in attendance on the practice of a recognised hospital, or in the military or naval services, or in medical and surgical practice. Each candidate must write an Essay, based on original research or observation, on some medical subject selected by himself, and approved of by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum so far as they are related to the subject of the Essay.

The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under forty years of age and shall have been in active practice for fifteen years as registered medical practitioners. They shall produce certificates of moral character from three registered members of the medical profession, and if they have not passed an examination in Arts previously to the Professional Examination in virtue of which they have been placed on the Register, they shall be required to pass in Classics and Mathematics. They will be examined in the Principles and

[2] This regulation will not apply to candidates registering as medical students on or after Oct. 1st, 1896. Such candidates must pass in all the subjects of the first examination.

Digitized by Google

Practice of Medicine, including Psychological Medicine, Hygiene, and Therapeutics, the Principles and Practice of Surgery, Midwifery, and Diseases of Women and Children, Pathology (Medical and Surgical), Anatomy (Medical and Surgical), Medical Jurisprudence, and Toxicology. The fee will be fifty guineas, of which twenty guineas will be returned if the candidate fails to satisfy the examiners.

Candidates for any of the above degrees must give at least twenty-eight days' notice to Professor Howden, Secretary, College of Medicine, Newcastle-on-Tyne.

VICTORIA UNIVERSITY.

Colleges of the University: Owens College, Manchester; University College, Liverpool; and Yorkshire College, Leeds.

Matriculation, which consists in signing the University Register, must precede entry upon any course of study in a College of the University, if that course is to be counted towards the required minimum of attendance for a degree. Those only can matriculate who are registered students of a College of the University.

Four degrees in Medicine and Surgery are conferred by the Victoria University—viz., Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M D.), and Master of Surgery (Ch.M.).

All candidates for degrees in Medicine and Surgery are required to pass an examination called the Entrance Examination in Arts, or to have passed such other examination as may be recognised by the University for this purpose.[4]

Degrees of Bachelor of Medicine and Bachelor of Surgery.—Before admission to the degree of M.B. or Ch.B. candidates are required to present certificates that they will have attained the age of twenty-one years on the day of graduation, and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in a College of the University, and one year at least having been passed in a College of the University subsequently to the date of passing the First M.B. Examination. All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations: the First Examination, the Second Examination, and the Final Examination.

The First Examination.—The subjects of examination are as follows:—(1) Chemistry; (2) Elementary Biology; (3) Physics. Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects. The Examination is divided into two parts: Part 1, Physics and Chemistry; Part 2, Biology; and the candidates may pass in these parts separately.

The Second Examination.—The subjects of examination are as follows:—A: (1) Anatomy; (2) Physiology, including Physiological Chemistry and Histology; B: (3) Materia Medica and Pharmacy. Candidates may pass in A or B separately. Candidates presenting themselves in A alone, or in B alone, and failing to satisfy the examiners, must present themselves again in the same subjects or in A and B together.

The Final Examination.—The subjects of examination are as follows:—(1) Pharmacology and Therapeutics. (2) General Pathology and Morbid Anatomy. (3) Forensic Medicine and Toxicology, and Public Health. (4) Obstetrics and Diseases of Women. (5) Surgery, Systematic, Clinical and Practical. (6) Medicine, Systematic and Clinical, including Mental Diseases and Diseases of Children.

Candidates may either present themselves in all the six subjects of examination on the same occasion, or may pass the examination in two parts, the first part consisting of *two* or *three* of the subjects (1), (2) and (3), the second part of the remaining subjects.

Candidates who fail to satisfy the examiners in the first part must either present themselves again in the subjects as selected or in all the six subjects of examination.

Candidates for the First Part of the examination must have completed the *fourth winter* of medical study.

Candidates for the Second Part of the examination, or for the whole examination, must have completed the fifth year of medical study.

Degree of Doctor of Medicine.—Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery, and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a printed Dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine. No candidate will be admitted to the degree unless his Dissertation shall have been recommended by the General Board of Studies to the Council for acceptance. Candidates may be examined on any subject connected with their dissertations.

Degree of Master of Surgery.—Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery, and at least one year has elapsed since they passed the examination for those degrees. The subjects of examination are as follows: (1) Surgical Anatomy; (2) Surgery; (3) Operative Surgery; (4) Clinical Surgery; (5) Ophthalmology; (6) Pathology and Bacteriology.

UNIVERSITY OF EDINBURGH.

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery.

Subject to regulations to be made from time to time by the University Court, the University may also confer diplomas in special branches of medical and surgical practice on graduates of the University in Medicine and Surgery.

Before commencing his medical studies each student must pass a preliminary examination in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek or French or German: Provided always that, in the case of a candidate whose native language is not English, an examination in the native language of the candidate may be substituted for one in either French or German, and an examination in any other classical language for one in Latin or Greek.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in Medical and Surgical study for five years. No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least one hundred lectures, or fifty lectures, as may be required by the regulations, and that the student has also duly performed the work of the class.

Candidates for the degrees of M.B. and Ch.B. must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than eighty patients and possesses a distinct staff of physicians and surgeons. They must have attended Clinical Surgery during a course or courses extending over not less than nine months. These courses may be conducted by the professor of clinical surgery, or by professors or lecturers appointed for the purpose by the University Court, or by the ordinary surgeons of the Royal Infirmary, Edinburgh, or of a general hospital defined and recognised as hereinbefore provided, and shall consist of regular instruction at the bedside, along with clinical lectures. A similar course of clinical medicine during a course or courses extending over not less than nine months is required. The candidate must have attended a course of instruction in Mental Diseases given by the University Lecturer, or by a recognised Teacher, consisting of not less than six Class-room meetings for lectures and demonstrations and ten meetings in the Wards of a recognised Asylum for the

[4] The examinations at present recognised are:—1. The Preliminary Examination of Victoria University, provided Latin and Mechanics have been taken up. 2. The Matriculation Examination of the University of London. 3. The Previous Examination of the University of Cambridge. 4. Responsions of the University of Oxford. 5. The Leaving Certificate Examination (Higher) and Local Examinations (Honors) of the Oxford and Cambridge Boards, provided that they include Latin, English, Mathematics, and Elementary Mechanics. 6. The First Examination for Graduation in Arts of any University in Great Britain and Ireland.

Digitized by Google

insane. The candidate must have attended a course of twenty-five meetings on Practical Pharmacy in a university or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society. The candidate must have attended, for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, or of a physician or surgeon, or of a member of the London or Dublin Society of Apothecaries. He must have acted as clerk in the medical wards and dresser in the surgical wards of a public hospital for a period of six months in each case; and must also have availed himself, to such an extent as may be required by the Senatus, with the approval of the University Court, of opportunities of studying, at a hospital or dispensary, Post-mortem Examinations, Fevers, Diseases of the Eye, Operative Surgery, and one of the two following, viz.—Diseases of Children, and Diseases of the Larynx, Ear, and Nose, or such other special departments as may from time to time be determined. The candidate must have attended, under the superintendence of a registered medical practitioner, twelve cases of labour, or such additional number as the Senatus, with the sanction of the University Court, may from time to time determine; or have attended for three months the practice of a lying-in hospital, or of the maternity department of a general hospital or other public charitable institution, and have conducted personally six or such an additional number of cases of labour as the Senatus, with the approval of the University Court, may from time to time determine. The candidate must have been properly instructed in Vaccination at a public vaccination station, by a public vaccinator, authorised by the proper Government authority to grant certificates of proficiency in vaccination.

Next, with respect to the places and institutions at which the studies of the candidate may be prosecuted, the following regulations have effect:—Two of the five years of medical study must be spent in the University of Edinburgh. The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign university recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. Of the subjects of study, sixteen in number—viz., Anatomy, Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than eight must be taken in the University of Edinburgh or in some other university of the United Kingdom, or in some Foreign or Colonial university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court, or in a college incorporated with, or affiliated to, a university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court.

Each candidate is examined, both in writing and orally, and clinically where the nature of the subject admits:—First, in Chemistry, Zoology, Botany, and Physics; second, in Anatomy, Physiology, Materia Medica and Therapeutics; third, in Pathology, and Medical Jurisprudence and Public Health; and fourth, in Surgery, Medicine, Midwifery, and clinically in Medicine and Surgery in a hospital. The examinations are conducted, as far as possible, by demonstrations of objects placed before the candidates. Candidates who profess themselves ready to submit to an examination in the first division of these subjects may be admitted to examination therein at the first period of examination after they have completed their attendance on the necessary classes. Candidates who have passed their examination in the first division of these subjects may be admitted to examination in the second division at the end of their third year. Candidates who have passed their examinations in the subjects comprised in the first and second divisions may be admitted to examination in the third division at the end of the fourth winter session. Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division when they have completed the fifth year of study.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £23 2*s.*, and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £6 6*s.*; for the Second Division (Anatomy, Physiology, and Materia Medica and Therapeutics), £6 6*s.*; for the Third Division (Pathology and Medical Jurisprudence and Public Health), £4 4*s.*; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, and Midwifery), £6 6*s.* The fee to be paid for the degree of Doctor of Medicine is £10 10*s.*, and the fee to be paid for the degree of Master of Surgery is £10 10*s.*

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and an examining body, but only candidates whose course conforms to Glasgow regulations can be admitted to examination. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers, but eight of the subjects other than clinical must be taken in this or some other recognised university entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations four degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D. and Ch.M. A Preliminary Examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, or French, or German, with possible options to students whose native language is not English in the case of the fourth subject, and on passing the Preliminary Examination candidates must register as medical students in the books of the General Medical Council. For the degrees of M.B. and Ch.B. a curriculum of five years is required, in each of the first four of which the student must attend at least two five months' courses, or alternatively one five months' course and two courses of two and a half months. The minimum of attendance in the first four years includes five months' courses in the following subjects:—Anatomy, Practical Anatomy (two courses), Chemistry, Materia Medica and Therapeutics, Physiology, Practice of Medicine, Surgery, Midwifery, and Diseases of Women and Infants, and Pathology; and courses of two and a half months in the following:—Practical Chemistry, Physics, Botany, Zoology, Practical Physiology, Practical Pathology, Medical Jurisprudence and Public Health. Candidates must attend at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least eighty patients and having a distinct staff of physicians and surgeons. At least nine months' hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted as clerk in medical and dresser in surgical wards, and must have had six months' out-door practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (twenty-five meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least twelve cases of labour, or three months of the practice of a Lying-in Hospital, six cases being personally conducted. The University also requires further study in Post-Mortem Examinations, Fevers, and Ophthalmology, and recommends study in other special subjects. If a candidate has completed in a University of the United Kingdom a course of study and passed an examination in Botany, Zoology, Physics or Chemistry, qualifying for a degree in Science or in Arts, he is held to have passed the examinations in such subject or subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry, to be taken after the completion of the included courses (candidates being at liberty to take two subjects at a time); the second comprising Anatomy, Physiology, and Materia Medica and Therapeutics, to be taken at the end of the third winter session; the third comprising Pathology, Medical Jurisprudence and Public Health, to be taken at the end of the fourth winter session; and the fourth or final, comprising Surgery, Clinical Surgery, Practice of Medicine, Clinical Medicine, and Midwifery, to be taken on completion of the fifth year of study.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under twenty-four years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on

Digitized by Google

completing the after course prescribed, including an examination in Clinical Medicine for M.D. and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

Fees.—The fees for M.B. and Ch.B. are £23 2*s*. The class fee in each subject of the curriculum for M.B. and Ch.B. is £3 3*s*. and the present fees for hospital attendance are £21. The fee for M.D. is £10 10*s*. (stamp duty being now abolished), and for Ch.M. £10 10*s*.

The great majority of the students take their hospital course at the Western Infirmary, where clinical instruction is given by professors of the University and other physicians and surgeons. Clinical instruction on Fevers is given at Belvidere Hospital, while special courses, largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Eye, the Ear, the Throat and Nose, and Insanity. Queen Margaret College, hitherto conducted as a separate institution for the higher education of women, has now been made over to the University, and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students are admitted to the Royal Infirmary.

Bursaries and Prizes to the annual amount of about £820 are appropriated to medical students, and Scholarships and Fellowships to the annual amount of about £1600 may be held by medical students who have gone through the Arts course.

Graduations under the regulations for the curriculum of five years introduced in 1892 began in July, 1897. Thus far students have been graduating as M.B. and C.M. on a four years' curriculum under the old regulations, and such graduates may afterwards proceed to the degree of M.D. by Thesis after passing a somewhat more stringent preliminary examination, including Greek. Supplementary regulations passed in 1895 by the Scottish Universities Commissioners allow those holding the degrees of M.B. and C.M. under the former regulations to proceed to the new M.D. by Examination and Thesis in the same manner as those who obtain the double Bachelorship under the new regulations. Candidates electing to proceed in this way will be freed from the preliminary examination in Greek.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are nearly the same as in the Universities of Edinburgh and Glasgow.

Professional Examinations will be held twice in each year—namely, in March and July, directly after the close of the winter and summer sessions.

The fees for graduation are the same as in the University of Edinburgh. Matriculation fee, including all dues, for the winter and summer sessions, £1 1*s*.; summer session alone, 10*s*. 6*d*.

Besides the Royal Infirmary, students have the opportunity of attending the following institutions: General Fever Hospital; Sick Children's Hospital; General Dispensary, and Lying-in and Vaccine Institutions daily; Royal Lunatic Asylum; Eye Institution, in which is given clinical instruction on Diseases of the Eye, and on the application of the Ophthalmoscope for their diagnosis.

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom only, after a special examination. The diploma can be entered on the Register of the General Medical Council.

Application for further information should be addressed to the Secretary of the Medical Faculty.

UNIVERSITY OF ST. ANDREWS.

The following are extracts from the Regulations for Degrees in Medicine contained in Ordinance No. 45 (St. Andrews, No. 4) of the Commissioners under the Universities (Scotland) Act, 1889 These regulations came into force on April 19th, 1897. Four Degrees in Medicine and Surgery shall be conferred by the University of St. Andrews—viz., Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The degrees of M.B. and Ch.B. shall always be conjoined. Before commencing his medical studies each student shall pass a Preliminary Examination in, (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects:—(α) Greek, (β) French, (γ) German, (δ) Italian, (ε) any other Modern Language, (ζ) Logic. A degree in Arts or in Science in any of the universities of the United Kingdom and in some colonial or foreign universities, shall exempt from the Preliminary Examination. The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St. Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects). Also the Final Examination for a degree in Arts or Science and the final examination for the Diploma of L.L.A.

Candidates for the degree of Bachelor of Medicine and Bachelor of Surgery must have been engaged in medical study for at least five years. In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months. During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court. The candidate must have received instruction in each of the following subjects of study, including such examinations as may be prescribed in the various classes—viz.: Anatomy, Practical Anatomy, Chemistry, Materia Medica, Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Practical Chemistry, Physics (including the the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine and Public Health. The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than eighty patients and possesses a distinct staff of physicians and surgeons, and is recognised for the purpose by the University Court. Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery (twelve cases of labour), and Vaccination.

With respect to the places and institutions at which the studies of the candidate may be prosecuted, the following regulations shall have effect:—1. Two of the five years of medical study must be spent in the University of St. Andrews. 2. The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court.

Women shall be admitted to graduation in Medicine, subject to the provisions of Ordinance No. 18 [General No. 9—Regulations for the Graduation of Women and for their Instruction in the Universities]: Provided always that every candidate for graduation shall produce evidence of having satisfied the conditions herein laid down with respect to the Preliminary Examination, and shall be examined in all the subjects necessary for graduation by the Examiners of the University of St. Andrews. All the classes necessary for graduation shall be taken in the University of St. Andrews, except in so far as instruction obtained elsewhere is allowed by the said Ordinance.

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery.—Each candidate shall be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz, First, in Botany, Zoology, Physics, and Chemistry: Second, in Anatomy, Physiology, and Materia Medica; Third, in Pathology, and Forensic Medicine and Public Health; Fourth, in Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine, and Midwifery.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court. The fee to be paid for the degree of Doctor of Medicine shall be 10 guineas, exclusive of any stamp duty which for the time may be exigible. The fee to

Digitized by Google

be paid for the degree of Master of Surgery shall be 10 guineas.

The following seven qualifying classes are now being taught at the United College, St. Andrews: (1) Physics, (2) Botany, (3) Natural History (Zoology), (4) Chemistry, (5) Anatomy, (6) Physiology, and (7) Materia Medica. These classes furnish two very complete Anni Medici—the period of university residence required by the four Scottish Universities for graduation in Medicine. The three last years of the medical curriculum can be taken at any convenient recognised Medical School in the United Kingdom. It is hoped that medical students who spend their two residential years at St. Andrews will return to their Alma Mater and graduate there. Owing to the munificence of the present Lord Rector—the Marquis of Bute—an important addition to the existing Medical Buildings is being made at a cost of from £8000 to £10,000.

Scholarships and Bursaries.—The following Scholarships and Bursaries for male and female Medical and Science Students are available at St. Andrews: One Scholarship of the annual value of £150, tenable for two years. A second Scholarship of the annual value of £100, tenable for one year and occasionally for two years. (The second Scholarship can be taken by students studying Physiology, Zoology, and Botany, in connexion with the Bachelor of Science degree.) Two Bursaries for male Medical students of the annual value of £50 each, for two years. Three Bursaries for male Medical students of the annual value of £20 each, for three years. Twenty Taylour Thomson Bursaries for female Medical students of the annual value of from £15 to £30 each, tenable for one or two years—viz.: Three Taylour Thomson Bursaries of the annual value of £30 each, tenable for two years. One of the annual value of £20, tenable for two years; eight of the annual value of £15 each, tenable for two years; two of the annual value of £30 each, tenable for one year; one of the annual value of £20, tenable for one year; five of the annual value of £15 each, tenable for one year. The Taylour Thomson Bursaries are Presentation Bursaries, and are awarded to female Medical students who pass the Preliminary Medical Examination at St. Andrews. The Bursaries are awarded in the order of merit, the most valuable ones being given to those students who obtain the highest marks in the Preliminary Medical Examination, and who are prepared to take two Anni Medici at the United College, St. Andrews.

For further particulars apply to the Dean of the Medical Faculty, University of St. Andrews, N.B.

UNIVERSITY OF DUBLIN (TRINITY COLLEGE).

Matriculation.—All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s.* is payable. No student can be admitted for the winter course after Nov. 25th.

Degrees in Medicine (M.B.), Surgery (B.Ch.), and Midwifery (B.A.O.).—Candidates for these degrees must be of B.A. standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation. The Arts course may be concurrent with the medical course, and the B.A. degree need not be taken before the final medical examination, but the medical degrees are not conferred without the Arts degree. The following courses must be attended:—(1) Lectures—Systematic, Practical and Applied Anatomy, Chemistry and Practical Chemistry, Surgery and Operative Surgery, Histology, Botany, Zoology, Physics, Physiology, Practice of Medicine, Midwifery, Pathology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene; (2) three courses of nine months' attendance on the Clinical Lectures of Sir Patrick Dun's or other recognised Dublin Hospital (one year at a recognised London or Edinburgh hospital before the commencement of the Dublin curriculum may be counted as one year spent in such Dublin hospital); (3) Practical Vaccination, one month's instruction; (4) Mental Disease, three months'; (5) Practical Midwifery with Clinical Lectures, including not less than thirty cases, six months'; (6) Ophthalmic Surgery, three months'. Two examinations have to be passed. The Previous Medical or Half M.B. Examination, including Physics and Chemistry, Botany and Zoology, Anatomy and Institutes of Medicine (Practical Histology and Physiology), may be passed when credit has been obtained for the corresponding subjects, and these may be taken separately if desired. The Final Examination is subdivided into five sections, comprising Applied Anatomy (Medical and Surgical), Applied Physiology, Jurisprudence and Hygiene, Materia Medica and Therapeutics, Medicine, Surgery, Pathology, Midwifery, Gynæcology, Obstetrical Anatomy, Clinical Medicine, Mental Diseases, Clinical Surgery, Operations, Clinical Ophthalmology. The first seven of these subjects may be passed in the fourth year and the last eight in the fifth year. Fee for the *Liceat ad Examinandum*, £10. Fee for the degrees, £17.

Doctor in Medicine.—A Doctor in Medicine must be M.B. of at least three years' standing, or have been qualified to take the degree of M.B. for three years, and must read a thesis before the Regius Professor of Physic. Total amount of fees for this degree, £13.

Master in Surgery.—A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years' standing, and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study, or study and practice, of his profession. He must then pass an examination in the following subjects:—1. Clinical Surgery. 2. Operative Surgery. 3. Surgical Pathology. 4. Surgery. 5. Surgical Anatomy (on the dead subject), and one of the following optional subjects:—1. Surgery in one of the following branches—viz., Ophthalmic and Aural, Gynæcological, and Dental. 2. Mental Disease. 3. Medical Jurisprudence and Hygiene. 4. Advanced Anatomy and Physiology. 5. Comparative Anatomy. Fee for the degree of Master in Surgery, £11.

Master in Obstetric Science.—A Master in Obstetric Science must have passed the M.B. and B.Ch. examinations, and produce a certificate of having attended a summer course in Obstetric Medicine and Surgery.[5] He is then required to pass an examination in the following subjects:—1. Practice of Midwifery. 2. Gynæcology. 3. Anatomy of Female Pelvis and Elementary Embryology. 4. Clinical Gynæcology. Fee for the degree of Master in Obstetric Science, £5.

University Diplomas.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in Medical Studies. The Course and Examination necessary for the diplomas are the same as for the degrees, except that the candidate is not required to attend the Lectures on Botany and Zoology, nor to pass the Previous Medical examination in those subjects. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor by attending the Lectures on Botany and Zoology, passing the Previous Medical examination in those subjects, and paying the degree fees. Fee for the *Liceat ad Examinandum*, £10. Fee for the diplomas in Medicine, Surgery, and Midwifery, £11.

ROYAL UNIVERSITY OF IRELAND.

All Degrees, Honours, Exhibitions, Prizes and Scholarships in this University are open to students of either sex.

Candidates for any degree in this University must have passed the Matriculation Examination. Students from other universities and colleges are included in this rule.

The following degrees, &c., are conferred by the University in this Faculty:—Bachelor of Medicine, Doctor of Medicine, Bachelor of Surgery, Master of Surgery, Bachelor of Obstetrics and Master of Obstetrics; in Sanitary Science, a special diploma; and in Mental Disease, a special diploma.

The Medical Examinations, except that for the diploma in Sanitary Science, will be held twice yearly—viz., in April and in October. The examination for the diploma in Sanitary Science will be held in July.

The course for degrees in Medicine, &c., is of at least five years' duration.

The First Examination in Medicine.—Students may not be admitted to this examination until the lapse of two academical years from the time of their matriculation. They must also have previously passed the First University Examination. The subjects of this examination are Natural Philosophy, Theoretic Chemistry, Zoology and Botany. The examination in each subject will comprise two parts:—1. A written examination. 2. Practical work and oral examination. For Chemistry the practical examination takes place at the close of the second year. Particular weight will be

[5] Existing graduates in Medicine of the standing of M.D. are not required to attend this course.

Digitized by Google

given to the practical part of the examination. Candidates at the First Examination in Medicine who at the First University Examination in Arts did not obtain 30 per cent. of the marks assigned to French or German will be required to present themselves for a qualifying examination in French or German. Failure to obtain 30 per cent. of the marks assigned to either of those languages will involve the loss of the examination.

The Second Examination in Medicine.—Students will be admitted to this examination after the lapse of one academical year from the time of passing the First Examination in Medicine, provided they have completed the second year of the medical curriculum. The subjects for this examination are Anatomy, Physiology, and Practical Chemistry.

The Third Examination in Medicine.—Students will be admitted to this examination after the lapse of one academical year from the time of passing the Second Examination in Medicine, provided they have completed the third year of the medical curriculum. The subjects for this examination will be Anatomy, Physiology, and Materia Medica (Pharmacology).

The Examination for the Medical Degrees.—Students will be admitted to this examination after the lapse of two academical years from the time of passing the Third Examination in Medicine, provided they have completed the course of medical studies prescribed for the fourth year. The examination consists of three parts or divisions:—(*a*) Medicine, including Therapeutics and Pathology, Mental Diseases, Medical Jurisprudence and Hygiene. (*b*) Surgery, Theoretical, Clinical, Operative; Surgical Anatomy, with Ophthalmology and Otology. (*c*) Midwifery and Gynæcology, with Diseases of Children. Each part of this examination must be passed as a whole. Upon completing satisfactorily his examination in all three divisions the candidate will, in addition to the parchment diplomas recording his admission to the Medical Degrees of M.B., B.Ch., and B.A.O., receive a certificate of having passed a qualifying examination in the subjects of Medicine, Surgery, and Midwifery. The fee for this certificate is £10, which must be paid prior to the candidate's admission to the Medical Degrees.

M.D. Degree.—Candidates may be admitted to this degree after the lapse of three academical years from the time of obtaining the degree of M.B. Every candidate will be examined at the bedside, and required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss all the questions arising thereon.

The M.Ch. Degree.—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. The examination for this degree will comprise Surgical Diseases and Surgery, both theoretical and operative; Surgical Anatomy; Ophthalmology and Otology; and will include—(*a*) a written examination; (*b*) a clinical examination; (*c*) an examination on Surgical Instruments and Appliances; and (*d*) an examination in Operative Surgery.

The Mastership in Obstetrics.—This degree will be conferred only on graduates in Medicine of the University of at least three years' standing. The examination will comprise the Theory and Practice of Midwifery and of Diseases of Women and Children and the Use of Instruments and Appliances and will include—(*a*) a written examination; (*b*) a clinical examination as far as practicable; (*c*) an oral examination, with practical illustrations; and (*d*) an examination on Instruments and Appliances.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.[6]

Regulations relating to the several Examinations applicable to Candidates who commenced their Professional Education on or after Jan. 1st, 1892.

Any candidate who desires to obtain both the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to complete five years of professional study at recognised Medical Schools and Hospitals and to comply with the following regulations and to pass the examinations hereinafter set forth.

Professional Examinations.—There are three Examinations, called herein the First Examination, the Second Examination, and the Third or Final Examination, each being partly written, partly oral, and partly practical. These examinations will be held in the months of January, April, July, and October, unless otherwise appointed. Every candidate intending to present himself for examination is required to give notice in writing to Mr. F. G. Hallett, Secretary of the Examining Board, Examination Hall, Victoria Embankment, W.C., fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates.

The subjects of the First Examination are—Chemistry and Physics, Practical Pharmacy, and Elementary Biology. A candidate may take this examination in three parts at different times. A candidate will be admitted to examination in Chemistry and Physics and Elementary Biology before registration as a medical student, and to examination in Practical Pharmacy on producing evidence of having been registered as a medical student by the General Medical Council, *or he may take Pharmacy* at any time during the curriculum. A candidate rejected in one part or more of the First Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected. If referred in Chemistry or Biology, he must produce evidence of further instruction at a recognised institution. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine on any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects in which he has passed.

The fees for admission to the First Examination are as follows: For the whole examination, £10 10*s.*; for re-examination after rejection in Part I. £3 3*s.*, and for re-examination in each of the other parts, £2 2*s.*

The subjects of the Second Examination are Anatomy and Physiology. Candidates will be required to pass in both subjects at one and the same time. Candidates will be admissible to the Second Examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of registration as Medical Students and after the lapse of not less than six months from the date of passing Parts I. and III. of the First Examination.

A candidate referred on the Second Examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his Anatomical and Physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the Second Examination are: £10 10*s.* for the whole examination, and £6 6*s.* for re-examination after rejection.

The subjects of the Third or Final Examination are: Part I. Medicine, including Medical Anatomy, Pathology, Practical Pharmacy, Therapeutics, Forensic Medicine, and Public Health. Candidates who have passed in Practical Pharmacy at the First Examination will not be re-examined in that subject at the Third Examination. Part II. Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances. Part III. Midwifery and Diseases peculiar to Women. Candidates may present themselves for examination in Midwifery and Diseases of Women at any time after the completion of the fourth year of professional study, not less than one year after passing the Second Examination, on production of the required certificates. Candidates may take this examination in three parts at different times, or they may present themselves for the whole examination at one time. They will be required to produce the following evidence before being admitted to any part of the Third, or Final Examination—viz., in Medicine, of having attended Lectures on Medicine, Pathology including Bacteriology, Pharmacology and Therapeutics, Forensic Medicine, and Public Health; Practical Instruction in Medicine; Medical Hospital Practice during two winter and two summer sessions; Demonstrations in the Post Mortem Room during twelve months; Clinical Lectures on Medicine during nine months; of having discharged the duties of Medical

[6] The diploma of Member of the Royal College of Surgeons of England and the Licence of the Royal College of Physicians of London are no longer granted separately except to students who commenced their professional study prior to Oct. 1st, 1884.

Digitized by Google

Clinical Clerk; Practice of a Fever Hospital and Clinical Demonstrations at a recognised Lunatic Asylum; in Surgery, of having attended Lectures on Surgery and Pathology including Bacteriology; Practical Instruction in Surgery; of having performed operations upon the Dead Subject; Surgical Hospital Practice during two winter and two summer sessions; Demonstrations in the Post Mortem Room during twelve months; Clinical Lectures on Surgery during nine months; of having discharged the duties of Surgical Dresser, and Clinical Instruction in Ophthalmology; in Midwifery of having attended Lectures on Midwifery; Practical Instruction in Midwifery; Clinical or other Lectures, with Practical Instruction in Diseases Peculiar to Women; and of attendance on 20 Labours.

Fees for admission to the Third or Final Examination are as follows: For the whole examination, £15 15*s*. Part I. For re-examination in Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health, £5 5*s*.; for re-examination in Practical Pharmacy (if taken at this examination), £2 2*s*. Part II. For re-examination in Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances, £5 5*s*. Part III. For re-examination in Midwifery and Diseases peculiar to Women, £3 3*s*.

A candidate referred on the Third or Final Examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re-examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference; and, in regard to Midwifery and Diseases peculiar to Women, a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher.

ROYAL COLLEGES OF SURGEONS AND PHYSICIANS OF EDINBURGH, AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or in Glasgow, or in Edinburgh and Glasgow, the student may obtain the diplomas of the three Bodies.

The three Bodies grant their Single Licences only to candidates who already possess another and opposite qualification in Medicine or Surgery, as the case may be, recognised by them. Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective Secretaries.

Professional Education.—1. Candidates who commenced medical study *before* Jan. 1st, 1892, must have been engaged in professional study during forty-five months from the date of registration as medical students by the General Medical Council, which period shall include not less than four winter sessions' attendance at a recognised medical school. 2. The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinct courses of instruction: Anatomy, during at least six months; Practical Anatomy, twelve months; Chemistry, six months; Practical or Analytical Chemistry, three months; Materia Medica, three months; Physiology, six months; Practice of Medicine, six months; Clinical Medicine, nine months; Principles and Practice of Surgery, six months; Clinical Surgery, nine months; Midwifery and the Diseases of Women and Children, three months; Medical Jurisprudence, three months; Pathological Anatomy, three months. The six months' courses delivered in Scotland must consist of not fewer than 100 lectures. The three months' courses must consist of not fewer than fifty lectures. The number of lectures certified as attended at any school not situated in Scotland should not be less than three-fourths of the total number of lectures delivered in a course. 3. The candidate must also produce the following certificates:—(*a*) Of having attended not less than six cases of labour, three of these to be conducted personally under the direct superintendence of the practitioner who signs the certificate, who must be a registered medical practitioner. (*b*) Of having attended, for three months, instruction in Practical Pharmacy; the certificate to be signed by the teacher, who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary, or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy. (*c*) Of having attended for twenty-four months the Medical and Surgical practice of a public general hospital containing on an average at least eighty patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. (*d*) Of having attended for six months (or three months, with three months' hospital clerkship) the practice of a public dispensary specially recognised by any of the above authorities; or the out-patient practice of a recognised general hospital, or of having acted for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities; this attendance should be made after the student has passed the First and Second Examinations. (*e*) Of having been instructed by a registered medical practitioner in the Theory and Practice of Vaccination, and of having performed operations under the teacher's inspection, during a period of not less than six weeks.

Candidates shall be subjected to three Professional Examinations, and they may enter either for the whole of an Examination or for a division thereof.

First Examination.—The First Examination shall embrace the two divisions of (1) Chemistry and (2) Elementary Anatomy and Histology, and shall take place not sooner than the end of the first year, including the period of a winter and a summer session. For the whole Examination taken at one time the sum of £5 5*s*. must be paid to the inspector of certificates not later than one week preceding it, after which no candidate will be entered. After rejection, for re-entry in all subjects, £3 3*s*.; for re-entry after obtaining exemption from re-examination in one or two subjects, £2 2*s*.; for entering for one division of subjects separately, £3 3*s*.; and for each re-entry after rejection, £2 2*s*. Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the First Examination before any of the boards specified in the Regulations will be exempt from examination in such subjects.

Second Examination.—The Second Examination shal embrace the three subjects of (1) Anatomy, (2) Physiology (3) Materia Medica and Pharmacy, each of which shall constitute a division of the examination, and may be entered for separately. The examination shall not take place before the termination of the summer session of the second year of study, including two winters and two summers. The fees for admission to this examination, payable not later than one week before the day of examination, are as follows:—For the whole Examination, £5 5*s*.; after rejection for re-entry in all subjects, £3 3*s*.; for re-entry after obtaining exemption from re-examination in one or two subjects, £2 2*s*.; for entering for one subject separately, £2 2*s*.; and for each re-entry therein after rejection, £2 2*s*. Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the Second Examination before any of the boards specified in the Regulations will be exempt from examination in such subject or subjects.

Final Examination.—The Final Examination shall embrace the three divisions of—(1) the Principles and Practice of Medicine (including Therapeutics, Medical Anatomy, and Pathology) and Clinical Medicine; (2) the Principles and Practice of Surgery (including Surgical Anatomy and Surgical Pathology) and Clinical Surgery; (3) Midwifery and Gynæcology, Medical Jurisprudence, and Hygiene (which divisions may be entered for separately at different times); and shall not take place before the termination of the full period of study. The fees for this Examination, payable not later than one week before the examination day, are as follows: For the whole Examination, taken at one time, in the case of candidates who have passed the First and Second Examinations, £15 15*s*., of which £10 10*s*. shall be returned to unsuccessful candidates. For entering for each of the three divisions of subjects separately, £6 6*s*., and on re-entry after rejection, £2 2*s*. in respect of each division or part thereof. This rule will also apply to any subsequent rejection. Any candidate admitted to the Final Examination, on the footing of having passed in the subjects of the First and Second Examinations at a recognised board, shall, on entering, pay the full fee of £26 5*s*.

All candidates shall be subjected, in addition to the Written and Oral Examinations, to Clinical Examinations

Digitized by Google

in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical Use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface Markings, &c.

REGULATIONS FOR CANDIDATES WHO COMMENCED STUDY *after* JANUARY 1ST, 1892.

In addition to the courses above prescribed candidates are required to attend the following courses: Physics, three months; Elementary Biology, three months; Diseases and Injuries of the Eye, three months; Insanity, three months; Infectious Diseases, three months; and twelve months Hospital Practice with Clinical instruction.

The curriculum lasts for five years; the fifth year should be devoted to clinical work at one or more public hospitals or dispensaries. Six months of the fifth year may be passed by the student as a pupil to a registered practitioner possessing such opportunities of imparting practical knowledge as may be deemed satisfactory by the Committee of Management. The student's regularity of attendance in the wards and out-patient departments of the hospitals and at the post-mortem examinations should be duly ascertained and noted on the certificate.

Candidates shall be subjected to four Professional Examinations:

First Examination.—The First Examination shall embrace the following divisions of subjects—(1) Physics, (2) Chemistry, and (3) Elementary Biology. The fees payable for admission to the First Examination shall be for the whole Examination, £5; for each division separately, £2 10*s.*

Second Examination.—The Second Examination shall embrace Anatomy and Physiology including Histology; and candidates may be admitted to this Examination at the end of the second year of medical study. The fees payable for admission to the Second Examination shall be—for the whole Examination, £5.

Third Examination.—The Third Examination shall embrace Pathology, Materia Medica, and Pharmacy. The fees payable for admission to the Third Examination shall be—for the whole Examination, £5; for re-entry in both subjects after rejection, £3.

Final Examination.—The Final Examination shall not be passed earlier than the end of the fifth year of study, and shall embrace the following subjects:—Medicine, including Therapeutics, Medical Anatomy, and Clinical Medicine; Surgery, including Surgical Anatomy, Clinical Surgery, and Diseases and Injuries of the Eye; Midwifery and Diseases of Women and of New-born Children; and Medical Jurisprudence and Hygiene. All candidates shall be subjected, in addition to the Written and Oral Examinations, to Clinical Examinations in Medicine and Surgery, which shall include the Examination of Patients, Physical Diagnosis, the Clinical use of the Microscope, Examination of the Urine and Urinary Deposits, Surgical Appliances, Bandages, Surface markings, &c. The fees payable for the Final Examination shall be,—for the whole Examination, £15, for re-entry in all subjects after rejection, £5.

There are six periods of Examination annually, four in Edinburgh and two in Glasgow, and candidates may present themselves at either examining centre irrespective of the place of the previous examination. The Registrar in Edinburgh is Mr. J. Robertson, 48, George-square; and the Registrar in Glasgow, Mr. A. Duncan, 242, St. Vincent-street, to whom fees and certificates must be sent.

Note.—In applying for copies of the Regulations students should state whether they commenced medical study before or after Jan. 1st, 1892.

ROYAL COLLEGE OF PHYSICIANS AND ROYAL COLLEGE OF SURGEONS IN IRELAND.

Two sets of Regulations are at present in force, under which examinations take place for the conjoint diploma of these bodies. The following Regulations are obligatory on all students commencing on or after Dec. 31st, 1891, the date already mentioned:—

PRELIMINARY EXAMINATION AND REGISTRATION.

Every candidate for the Conjoint Examinations of the Colleges shall produce evidence—(*a*) of having, before entering on medical studies, passed a Preliminary Examination in general education recognised by the General Medical Council; and (*b*) of having been registered by that Council as a Student in Medicine. Each candidate before receiving his diplomas must produce a registrar's certificate or other satisfactory evidence that he has attained the age of twenty-one years.

Preliminary Examination.—The subjects for examination are identical with those prescribed for the Preliminary Examination by the General Council of Medical Education and Registration.

Professional Examinations.

Every candidate is required to pass four Professional Examinations—at the end of the first, second, fourth and fifth years of his professional studies. No candidate shall be admitted to the Final or Qualifying Examination within three months of his rejection at the Final or Qualifying Examination by any other licensing body. All examinations shall be conducted as far as possible by demonstration of objects placed before the candidates.

First Professional Examination.—Every candidate is required, before admission to the First Professional Examination, to produce evidence—(1) of having passed in the subjects of the Preliminary Examination; (2) of having been registered as a medical student by the General Medical Council; and (3) of having attended a course of—(*a*) Demonstrations and Dissections, (*b*) lectures on Theoretical Chemistry, winter courses; (*c*) Practical Chemistry, three months' summer or winter course; (*d*) Elementary Biology; (*e*) Physics. [*Note.*—Biology and Physics may be studied either before or after registration at institutions recognised for the purpose by the Colleges.] (*f*) Practical Pharmacy—(1) evidence of attendance for three months in the compounding department of a clinical hospital, which hospital shall have satisfied the committee of management that its means of instruction are sufficient, and shall return to the committee the names of its students at the commencement of the course, together with a record of their attendance at its close; or (2) evidence of attendance on a course of Practical Pharmacy in a recognised medical school, the course to consist of not less than twenty demonstrations; or (3) evidence of having served a full apprenticeship of three years, or of having acted as paid assistant for not less than one year, in the establishment of a Licentiate apothecary or of a registered pharmaceutical chemist. The fee for this examination is £15 15*s.*

The subjects of the First Professional Examination are the following:—1. (*a*) Chemistry; (*b*) Physics. 2. Practical Pharmacy. 3. Elementary Biology. 4. Anatomy—viz., Bones, with attachments of Muscles and Ligaments, and Joints. Candidates may take this examination as a whole at one time or in four parts, but no portion earlier than the end of the first winter session.

Second Professional Examination.—Candidates are not admissible to this examination before the end of their second winter session. Every candidate is required, before admission to the Second Professional Examination, to produce evidence of having passed the First Professional Examination; also certificates of having attended—(1) a medico-chirurgical hospital for nine months; (2) Demonstrations and Dissections for six months; (3) Practical Histology for three months; (4) Lectures on (*a*) Anatomy for six months; (*b*) Physiology for six months; (*c*) Materia Medica for three months. Materia Medica may be deferred to the third year. The fee for this examination is £10 10*s.*

The subjects of the Second Professional Examination are the following:—1. Anatomy: the anatomy of the whole human body; (2) Histology; (3) Human Physiology; (4) Materia Medica. The candidate must present himself, in the first instance at least, in Anatomy and Histology; if he pass in either of these subjects he may, at the discretion of the examiners, get credit therefor. Physiology and Materia Medica may, at the option of the candidate, be passed at the end of the second or during the third year.

Third Professional Examination.—Candidates are not admitted to this examination before the end of their fourth winter session. Every candidate is required, before admission to the Third Professional Examination, to produce evidence of having passed the Second Professional Examination; also, in addition to the certificates required for the Second Professional Examination, certificates of having attended—(1) a medico-chirurgical hospital for eighteen months; (2) a midwifery hospital or maternity for six months, including evidence of having been present at thirty labours;[7] (3) clinical instruction in Mental Diseases

[7] May be taken in either the fourth or fifth year.

Digitized by Google

at an institution recognised by the Colleges[7] for three months; (4) Operative Surgery, including operations on the Dead Subject, not less than thirty meetings of the class; (5) Demonstrations and Dissections, for six months; (6) Vaccination;[7] (7) Practical Pathology, not less than thirty meetings of the class; (8) Lectures on (*a*) Medicine for six months; (*b*) Surgery for six months; (*c*) Public Health and Forensic Medicine for three months; (*d*) Midwifery, including Diseases peculiar to Women and to New-born Children, for six months. Nos. 2, 3, and 6 may be deferred to fifth year. Satisfactory evidence must be produced of attendance in fever wards in connexion with the hospital attendance in either the third or a subsequent year. The fee for this examination is £9 9*s*.

The subjects for the Third Professional Examination are the following:—(1) Medicine; (2) Surgery; (3) Pathology; (4) Therapeutics; (5) Public Health and Forensic Medicine. A candidate must present himself, in the first instance at least, in Medicine, Surgery, and Pathology. Should he pass in either Medicine or Surgery he shall get credit therefor, even if he have failed in other parts of the examination.

Final Professional Examination.—Candidates are not admissible to this examination before the end of their fifth year of medical study. Every candidate is required before admission to produce evidence—(1) of having passed the Third Professional Examination; (2) of having attended—(*a*) Clinical Instruction in Ophthalmic and Aural Surgery for three months; (*b*) a midwifery hospital or maternity, if not taken in the fourth year, for six months; (*c*) Vaccination, if not taken in the third or fourth year; (*d*) Clinical Instruction in Mental Diseases, if not taken in the fourth year.

The subjects for the Fourth Professional Examination are the following:—(1) Medicine, including Medical Anatomy and Mental Diseases; (2) Surgery; (3) Operative Surgery and Surgical Anatomy; (4) Ophthalmic and Aural Surgery; (5) Midwifery, including Diseases of Women and New-born Children; and (6) the Theory and Practice of Vaccination. Every candidate shall produce evidence of having acted as medical clinical clerk and as surgical dresser. Candidates may present themselves for examination in *all* the subjects of the Final Examination at the *same* time, or in one or more of the following groups:—(*a*) In Medicine, including Mental Diseases, Medical Anatomy, and Clinical Medicine; (*b*) Surgery, including Ophthalmic and Aural Surgery, Clinical Surgery, Operations, and Surgical Anatomy; (*c*) Midwifery, including Diseases of Women and New-born Children, and the Theory and Practice of Vaccination. Candidates must pay the full fee before being admitted to any part of the examination. Candidates may take the groups in any order they please. The fee for this examination is £6 6*s*.

SOCIETY OF APOTHECARIES OF LONDON.

There are three examinations—Primary; Final, Section I.; and Final, Section II. The Primary Examination is held quarterly, on the first Wednesday and on the Monday and Thursday of the same week, in the months of January, April, July, and October. Final Examinations are held monthly.

The Primary Examination consists of two parts. Part I. includes Elementary Biology; Chemistry, the Principles of the Science which bear on the Study of Medicine; Chemical Physics, including the Elementary Mechanics of Solids and Fluids, Heat, Light, and Electricity; Practical Chemistry; and Pharmacy. A synopsis indicating the range of the subjects in the examination will be sent with the regulations on application. Evidence of instruction in these subjects must be produced prior to examination. Part II. includes Anatomy, Physiology, and Histology. This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one. Evidence must be produced of the candidate's course of study. A schedule for the Primary Examination, to be obtained of the Secretary, must be signed by the Dean of the Medical School or other authority. Section I. of the Final Examination consists of three parts. Part I. includes the Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy. Part II. includes the Principles and Practice of Medicine, together with Therapeutics, Pharmacology, and Prescriptions; Pathology and Morbid Histology; Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children and the Use of Obstetric Instruments and Appliances. Part III. may be postponed to Section II. of the Final Examination, and candidates may enter for Parts I., II., and III. together or separately. Section I. of the Final Examination cannot be passed before the expiration of forty-five months after registration as medical student, during which time not less than three winter sessions and two summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the Court of Examiners. Section II. of the Final Examination consists of three Parts. Part I. includes an Examination of and Written Report on Surgical Cases, and Operative Manipulation and Surgical Anatomy, Instruments and Appliances. Part II. includes an Examination of and Written Report on Medical Cases and Medical Anatomy. Part III. includes Midwifery, Gynæcology, and Diseases of New-born Children, and the Use of Obstetric Instruments and Appliances. Parts I. and II. of this examination cannot be passed before the end of the fifth year.

The course of study for the Primary Examination is as follows:—Elementary Biology, not less than three months; Chemistry and Chemical Physics, six months; Practical Chemistry, three months; Pharmacy and Dispensing, three months; Anatomy, six months; Practical Anatomy with Demonstrations, twelve months; Physiology, six months; Histology with Demonstrations, three months. The study of these subjects must be pursued at a Medical School or at a place of instruction recognised by the Society. Evidence of having received instruction in Biology and Chemistry before registration as medical student will be admitted. Instruction in Pharmacy and Dispensing must be given by a registered medical practitioner or by a member of the Pharmaceutical Society by examination or in a public hospital, infirmary, or dispensary.

The course of study for the Final, Section I., Examination includes attendance on the Surgical and Medical Practice (with Post-mortem Examinations) at a hospital connected with a medical school for a period of three winter and two summer sessions; lectures on the Principles and Practice of Surgery, six months; Practical Surgery, three months; Clinical Surgical Lectures, nine months; Dressership,[8] six months; Performance of Surgical Operations on the Dead Body; lectures on Principles and Practice of Medicine, six months; Pathology, three months; Clinical Medical Lectures, nine months; Clinical Clerkship,[8] six months; Forensic Medicine, Hygiene, and Insanity, three months; Midwifery and Gynæcology, three months; Clinical Instruction in the same, three months; a course of Practical Midwifery; attendance on twenty Midwifery cases. The course of medical study must extend over the above-mentioned period of forty-five months.

The course of study for the Final Examination Section II. includes either attendance on the Practice of Medicine and Surgery at a hospital or other institution recognised by the Society for a further period of twelve months, or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at two special hospitals for six months (three months at each hospital), and for six months at a general hospital, all such hospitals to be recognised by the Society. Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects: Ophthalmic Surgery, Laryngology with Rhinology and Otology, Dermatology, and Diseases of Children. These courses may be taken at a general hospital recognised by the Society any time after the student has held the post of Dresser and Clinical Clerk. No candidate is eligible for the Final Examination who has not completed the curriculum prescribed by the Society, in evidence of which a schedule, to be obtained of the Secretary, must be produced, signed by the Dean of the Medical School or other authority. Prior to Section II. of the Final Examination the candidate must produce certificates: (1) of being twenty-one years of age; (2) of moral character; (3) of the course of medical study; and (4) of proficiency in vaccination signed by a teacher

[8] These offices may be held at a hospital, infirmary, or dispensary where sufficient opportunities are afforded for the acquirement of practical knowledge.

Digitized by Google

authorised by the Local Government Board. Candidates intending to present themselves for examination are required to give fourteen days' notice. A form for this purpose will be sent on application.

The fee for the three examinations is 15 guineas, or 5 guineas for each examination, except in the case of persons holding a foreign diploma, who are required to pay the entire fee of 15 guineas. The Secretary to the Examiners attends at the Hall of the Society, Blackfriars, E.C., from 10 to 12 o'clock daily.

CONJOINT EXAMINATIONS OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND AND APOTHECARIES' HALL.

These examinations are now only carried on for the candidates who entered previously to the year 1895 in this scheme. Examinations are held bi-annually. Communications in connexion therewith should be addressed to the Secretary of the Conjoint Board, Dr. Woods, Merrion-square East.

Apothecaries' Hall of Ireland.—This body is now empowered to grant examinations in connexion with examiners in Surgery appointed by the General Medical Council, and by the direction of the Privy Council to hold examinations in a similar manner to the Apothecaries' Hall of London. The qualification entitles the holder to register under the Medical Act of 1886, and is a qualification in Medicine, Surgery, and Midwifery, and to act as an Apothecary. It also qualifies for appointments in the Naval Service, Military Service, and Poor-law appointments and Colonial appointments. It will be divided into four professional examinations, the first of which is to be held early in October and at intervals of three months; the final examinations twice a year. The regulations will be issued on Sept. 1st.

UNIVERSITY OF BRUSSELS.

British and other practitioners holding registrable qualifications are admissible for the Doctorate of the University of Brussels without further curriculum. Candidates should appear with their diplomas at the Secretary's office not later than 2 P.M. on the day preceding the examination. The fees are—For matriculation, £8 12*s.*; for 1st Part, £4 8*s.*; for 2nd Part, £4 4*s.*; for 3rd Part, £4 8*s.*; for legalisation of diploma, 8*s.*—£22. Unsuccessful candidates may present themselves again three months after rejection. Candidates who have paid in advance the fees for the three examinations, and are unsuccessful in the first, recover the fees paid for the second and third; those who fail in the second recover the fees paid for the third examination. There are three examinations, viz.—1st Part: Medicine, Pathology, and Morbid Anatomy; General Therapeutics; Materia Medica and Pharmacology; Special Therapeutics and Mental Diseases. 2nd Part: Surgery; Midwifery; Hygiene; and Medical Jurisprudence. 3rd Part: Clinical Examination in Medicine at the Hospital; Clinical Surgical Examination; Examination in Midwifery, consisting of obstetrical operations on the mannequin (model of pelvis); Examination in Operative Surgery, consisting of some of the usual operations on the dead subject, such as Amputation, Ligature of an Artery, &c.; Regional Anatomy on the Dead Body, with Dissections; and Ophthalmology. Great importance is attached to practical knowledge, but candidates must also possess sound theoretical knowledge. The standard required varies with the subject. The examinations, which are entirely *vivâ voce*, take place on the first Tuesday in November, December, February, May, and June. Candidates have the option of passing each Part separately or of taking the three together, and the latter is the usual course. The time required for the three examinations seldom exceeds ten days, and is usually less. They are conducted in English. There are in England at present about 600 graduates holding this degree, and an English Association of Brussels Graduates has been formed.

Further information may be obtained from Mr. Walter Reeve, 38, Manchester-street, Manchester-square, W.

THE ARMY, NAVY, AND INDIAN MEDICAL SERVICES.

Consequent upon the issue of the Royal Warrant of August, 1891, alterations have taken place in the designations of the departmental rank of the officers of the Army Medical Staff, and medical officers are also now placed, as regards sick leave of absence on full pay, on the same footing as those laid down for regimental officers. By a subsequent Royal Warrant, dated Nov. 10th, 1891, Art. 1208*b* of the Pay Warrant was revised by inserting the words "an officer of our Medical Staff" after the words "combatant officer," thus giving medical officers an equal title with combatant officers to reckon time on half-pay towards retirement, when the half-pay has been due to ill-health contracted in the performance of military duty. Under the Royal Warrant of July, 1895, time on half-pay not exceeding a year may under similar circumstances also reckon towards promotion. The substantive ranks of officers of the Medical Staff carry precedence and other advantages attaching to the rank indicated by the military portion of it, with such exceptions and within such limits as are laid down in the earlier Warrant.

In the *Gazette* of Aug. 28th, 1891, it was announced that the Queen had been pleased, by Royal Warrant, dated Aug. 7th, 1891, to approve of the following alterations of the designations of the departmental rank of the officers of the Medical Staff now serving as follows:—Surgeons-General, ranking as Majors-General, to be Surgeon-Major-Generals; Deputy Surgeons-General, ranking as Colonels, to be Surgeon-Colonels; Brigade-Surgeons, ranking as Lieutenant-Colonels, to be Brigade-Surgeon-Lieutenant-Colonels; Surgeons-Major, ranking as Lieutenant-Colonels, to be Surgeon-Lieutenant-Colonels; Surgeons-Major, ranking as Majors, to be Surgeon-Majors; Surgeons, ranking as Captains, to be Surgeon-Captains. The substantive rank of the Director-General of the Army Medical Department is that of Surgeon-Major-General.

[For the text of the Warrant of Aug. 7th for the Medical Staff, *vide* THE LANCET of Aug. 22nd, 1891, page 459 *et seq.*]

Admission into the Army and Indian Medical Services is gained as the result of competitive examination. Under special conditions the admission may take place by nomination under the authority of the Secretary of State for War. Candidates for both services must, before being admitted to examination, possess a double qualification to practise Medicine and Surgery, and be registered under the Medical Act. They are also now required to produce certificates of having acted as a medical clinical clerk for six months, as surgical dresser for another six months, and of having had not less than three months' instruction at an ophthalmic hospital or the ophthalmic department of a general hospital, including a course on errors of refraction. They must also furnish satisfactory certificates of moral character. A candidate for the Army must be between the ages of twenty-one and twenty eight, in good mental and bodily health, and must sign a declaration upon honour that he is of pure European descent; for the Indian Service a candidate must be between twenty-one and twenty-eight, of sound bodily health, and a natural-born subject of Her Majesty. Both are examined as to physical fitness by a Board of Medical Officers. These conditions being satisfied, the candidate is admitted to the competitive examination, which is usually held in London twice a year, in the months of February and August. An entrance fee of £1 is required from each candidate admitted to the competition, and is payable at the conclusion of the candidate's physical examination, if he be pronounced fit. No candidate for the Indian Service will be allowed to compete on more than three occasions. The subjects of examination are divided into *compulsory* and *voluntary*. The former comprise Surgery (1200 marks), Medicine, including Therapeutics and the Diseases of Women and Children (1200 marks), Anatomy and Physiology (600 marks), Chemistry and Pharmacy, and a practical knowledge of Drugs (600 marks). The examination in Medicine and Surgery will be in part practical, and will include operations on the dead body, the application of surgical apparatus, and the examination of medical and surgical patients at the bedside. The eligibility of the candidate for admission into the service is determined by the result of this part of the examination. By an Army Order dated May 1st, 1895, no candidate shall be considered eligible who shall not have obtained at least one-third of the marks obtainable in each of the compulsory subjects, and at least one-half of the aggregate of marks for all the compulsory subjects. The *voluntary* subjects are French (200 marks), German (200 marks), and Natural Sciences: (*a*) Physics (300 marks); (*b*) Zoology (300 marks); (*c*) Geology and Physical Geography (300 marks); and (*d*) Botany (300 marks); and for the Indian

Digitized by Google

service Hindustani (200 marks). A candidate may not present himself for examination in more than two of the subjects included under the term "Natural Sciences." A number less than one-third of the marks obtainable in each of the voluntary subjects will not be allowed to count in favour of a candidate who has qualified in the compulsory subjects. Although the results of the examination in voluntary subjects do not affect the question of the eligibility of the candidate for a commission, they influence his position on the list, which is determined by the numbers obtained under the two heads conjointly. After having passed this examination, the successful candidates for both services are sent to the Army Medical School at Netley as "surgeons-on-probation," receiving a daily pay of 8*s.* and certain allowances, to go through a four months' course of instruction in the special duties required of them in the service. The staff of the school consists of four professors, all of them men of high standing in their special departments. The Professorship of Military Medicine is held by Deputy Surgeon-General Henry Cayley, I.M.S. Brigade-Surgeon-Lieutenant-Colonel W. F. Stevenson, M.S., is Professor of Military Surgery; Brigade-Surgeon-Lieutenant-Colonel J. L. Notter, M.D., of Military Hygiene; and Dr. A. E. Wright, of Pathology. There is an Assistant Professor for each of these subjects who is an Army Medical Officer. The lectures on Military Surgery include gunshot and other wounds, transport of sick and wounded, duties of army medical officers in the field, on board troopships and transports, recruiting, and other duties incident to military service. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war, at home and abroad, the management of lunatics under the conditions of military service, &c. The course of six lectures on Lunacy and Military Asylum work is delivered at the Netley Lunatic Asylum by Brigade-Surgeon-Lieutenant-Colonel Irving. The course of Hygiene comprises the examinations of water and air, the general principles of diet, with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the consideration of the clothing, duties, and exercises of the soldier, and the circumstances affecting his health, with the best means of preventing disease, and instruction in the mode of preparing the various statistical and other returns required of the medical officer. The Pathological course includes bacteriology and demonstrations in physiological chemistry. The surgeons-on-probation are detailed for duty in the wards of the hospital, under the Professors and Assistant Professors of Medicine and Surgery. They spend two months in the medical and two months in the surgical division of the hospital, and there they are taught practically the details of the management of patients in a military hospital, the registration of their diseases, the duties of invaliding, the modes of filling up the regulation statistical returns and other service documents. The surgeons-on-probation are provided with quarters and are extra members of the mess at Netley. After having passed through the course of instruction they are examined on the subjects taught in the school, and their position on the list of those recommended for commissions is determined by the combined results of the competitive and final examinations. At the close of each session eight prizes are awarded: the Herbert Prize of £20 to the surgeon-on-probation who has obtained the highest number of marks at the Netley examination; the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination in Hygiene; the De Chaumont prize of books to the one who takes second place in Hygiene; the Martin Memorial Gold Medal for the highest number of marks in the examination on Military Medicine; the Montefiore Medal and £21, awarded for Military Surgery; the Montefiore Second Prize, a revolver to the surgeon-on-probation who obtains the second highest number of marks in this branch; the Maclean prize of books for Clinical Medicine and Surgery and for Ward Work; and a prize of books for the highest number of marks gained in Pathology.

At the close of the Netley Session those surgeons-on-probation who have obtained one-third of the possible total of marks in each subject are recommended for commissions as Surgeon-Lieutenants. The Surgeon-Lieutenants of the British Medical Service pass on from Netley to Aldershot, where they go through a systematic course of instruction in company and ambulance drill and equitation. The surgeons of the Indian Medical Service do not go to Aldershot, but undergo, whilst at Netley, a course of instruction in company and ambulance drill and in other military duties. The position of the officers of the Indian Service on the list of Surgeon-Lieutenants is determined by the combined results of the London and Netley examinations, and, as far as the requirements of the service permit, they have the choice of commands in India—i.e., Bengal, Punjab, Madras, or Bombay—according to their position in that list. All officers appointed to the Indian Medical Service are now placed on one list. Though ordinarily employed within the limits of the command to which they are posted, they are liable for employment in any part of India.

The Army Medical Staff.—Surgeon-Lieutenants, if duly recommended, are promoted to be Surgeon-Captains on completing three years' full-pay service.

Surgeon-Captains, if recommended by the Director-General, are promoted to be Surgeon-Majors on completing twelve years' full-pay service, of which three must have been passed abroad. Before being promoted they will be required to pass an examination. This examination may be taken at any time after their seventh year of service. It will embrace the following subjects: (*a*) Surgery and Surgical Anatomy; (*b*) Medicine and Pathology; and (*c*) Hygiene, within the limits treated of in "Notter and Firth's Practical Hygiene," also the regulations regarding the sanitation of garrisons, quarters, hospitals, &c., as well as of camps and hospitals in the field, and of transports, troop and hospital ships; (*d*) duties of medical officers at home and abroad and at sea, as defined in the regulations, also hospital organisation and administration in peace and war, including the transport of sick and wounded by land and sea; (*e*) and the administration, interior economy, command, and discipline of the Medical Staff Corps, together with a knowledge of the principles of military law and their practical application (a certificate of proficiency in military law obtained at a garrison class will exempt the holder from examination in the latter).

A certificate will be required from a recognised teacher of surgery in any medical school, at home or abroad, in which operative surgery is taught, showing that the medical officer has gone satisfactorily through a complete course of operative surgery during the period within which the examination must be taken, and that he is a competent operator.

A report on any subject of a practical professional character, to be selected by the officer himself, and certified to be his own composition and in his own handwriting, will also be required. Considerable importance will be attached to the literary and scientific merits of this report, which must be furnished before the officer completes twelve years' service.

The examinations will be conducted by printed questions, which will enter so far into the subject matter of each head selected for examination as to show that the officer's knowledge has been fully tested.

The questions and answers will be forwarded, under a sealed confidential cover, to the Director-General for transmission to the examiners, who will report to the Director-General as to the competence of the officer examined.

The examination in Medicine and Surgery will be held by two gentlemen appointed by the Secretary of State; that in Hygiene by the Professor of Hygiene, Army Medical School, Netley; and that in Regulations, Duties, Military Law, &c., by an administrative medical officer, nominated for the purpose by the Director-General.

Any higher qualification, such as M.D., F.R.C.S. &c., or any diploma in Hygiene and State Medicine, taken after May 1st, 1890, will not exempt Surgeon-Captains from this examination.

Surgeon-Majors are, if duly recommended, promoted to be Surgeon-Lieutenant-Colonels on completing twenty years' full-pay service.

The selection of Surgeon-Lieutenant-Colonels for advancement to the grade of Brigade-Surgeon-Lieutenant-Colonel is made on the grounds of ability and merit (on the recommendation of the Commander-in-Chief), in determining which the following points will be considered:—The officer to be so selected must have been favourably reported on by the several military and departmental officers under whom he may have served, as set forth in their Annual Confidential reports. He must be physically fit for general service and have served abroad for at least eight years.

Digitized by Google

A Brigade-Surgeon-Lieutenant-Colonel, to be eligible for selection as Surgeon-Colonel, must have served abroad at least ten years, of which three must have been in India. All promotions from the rank of Brigade-Surgeon-Lieutenant-Colonel to that of Surgeon-Colonel, and from the rank of Surgeon-Colonel to that of Surgeon-Major-General, shall be given for ability and merit, upon the selection of the Commander-in-Chief, with the approval of the Secretary of State, and the grounds of such selection shall be stated in writing. In all such cases the amount of service abroad shall be expressly stated. All officers under the rank of Surgeon-Colonel are placed on the retired list at the age of fifty-five, and those of that rank and of the rank of Surgeon-Major-General at the age of sixty, except that in any particular case in which it may be considered necessary for the interest of the public service the age of retirement of a Surgeon-Major-General may be extended for a period not exceeding two years. From recent promotions which have been made it is evident that Surgeons-Colonel who have passed the age of fifty-seven before being selected for the rank of Surgeon-Major-General will be passed over in favour of younger officers who can, by reason of age, serve a full three years in the rank of Surgeon-Major-General.

Foreign Service.—Army Order 85 of June, 1897, states that the periods of service abroad, reckoning from the date of embarkation at home, will (except in the case of a Surgeon-Major-General or Surgeon-Colonel) be five years for all stations abroad (except that on the west coast of Africa), unless such period should be incompatible with the interests of the public service.

Sick Leave.—An officer of the Army Medical Staff may be allowed full pay during sick leave of absence on the same conditions as those laid down for regimental officers.

Service on the West Coast of Africa.—Officers who entered the Army Medical Staff, or volunteered expressly for service on the West Coast of Africa on or after the 1st of March, 1873, receive double pay while actually serving on the Coast. Candidates who present themselves expressly for service in the Army Medical Staff on the West Coast enter under the same qualifications as other candidates, except that they may be admitted up to thirty years of age. After 3 years' actual service on the coast they are eligible for general service. If, however, it be certified by a medical board that any such officer is unfit for further duty on the coast he shall be eligible for general service, though he may not have completed 3 years' service there. For each year's service on the coast an officer is entitled to a year's leave at home. Each year or portion of a year served on the West Coast reckons double towards voluntary retirement or retired pay, provided that an officer has served 12 months on the coast.

Indian Medical Service.—Officers on appointment are, when possible, provided with passage to India by troopship; when troopship accommodation is not available passage at the public expense is provided by steamer, or a passage allowance granted if preferred. A charge for messing during the voyage is made at the rate of 2*s.* a day. This payment does not include the cost of liquors, which are charged for as extras. Any officer who may neglect or refuse to proceed to India under the orders of the Secretary of State for India within two months from the date of leaving Netley will be considered as having forfeited his appointment, unless special circumstances shall justify a departure from this regulation. The alteration of titles of medical officers in the Indian Service, so as to assimilate them to those of the Army Medical Staff, was promulgated in a Royal Warrant dated Dec. 7th, 1891. The articles of this Warrant were ordered to take effect from Aug. 7th, 1891, the date of the Medical Staff Warrant. By this Warrant the ranks of the medical officers in the Indian military forces were declared to be substantive ranks, and to carry with them the same precedence and other advantages as the corresponding ranks in the Army Medical Staff, including command over the medical officers and subordinates, native and European, engaged in hospital service. The function of military command is subject to the same restrictions as in the British service. An important provision of this Warrant is that Surgeon-Lieutenants "shall be promoted" to the rank of Surgeon-Captain on completing three years' full-pay service, Surgeon-Captains to the rank of Surgeon-Major after twelve years' service, and Surgeon-Majors to the rank of Surgeon-Lieutenant-Colonel after twenty years' service. No examination to qualify for promotion is required. All promotions to higher grades are to be given by selection for ability and merit. In case of distinguished service in the field a medical officer may be at once promoted from any rank to the one next above it. The ages for compulsory retirement are the same as those for the Medical Staff. Officers of the Indian Medical Service below the rank of Surgeon-Colonel may be granted: 1. Privilege leave under such regulations as may from time to time be in force. 2. Leave out of India for no longer period than one year, capable of extension to two years' absence from duty, on the following pay:—After arrival in India, on first appointment, £200 a year; after the commencement of the fifth year's service for pension, £250 a year; after the commencement of the tenth year's service for pension, £300 a year; after the commencement of the fifteenth year's service for pension, £400 a year; after the commencement of the twentieth year's service for pension, £450 a year; and after the commencement of the twenty-fifth year's service for pension, £500 a year. 3. Leave in India, but for the period of one year only, on full military pay and half the staff salary of appointment. No extension of leave involving absence from duty for more than two years, whether taken in or out of India, can be granted except on specially urgent grounds and without pay. An officer unable on account of the state of his health to return to duty within the maximum period of two years' absence, unless he is specially granted an extension of leave without pay, is placed on temporary half-pay or the retired list, as the circumstances of the case may require. An officer is also liable to be placed on half-pay or the retired list should his health require an undue amount of leave, whether in or out of India. Leave may be granted at any time, but solely at the discretion of the Commanders-in-Chief or of the Local Governments in India in the case of officers not under the direct orders of a Commander-in-Chief. Officers of the Administrative grades may be granted one period of leave not exceeding eight months during their tenure of appointment.

Naval Medical Service.—A candidate must be between the ages of twenty-one and twenty-eight, and must be the son of parents of pure European blood. He must declare his readiness for general service at home or abroad. Candidates will be examined by the Board in the following compulsory subjects: (*a*) Medicine, including Therapeutics and Diseases of Women and Children, 1200 marks; (*b*) Surgery, 1200 marks; (*c*) Anatomy and Physiology, 600 marks; and (*d*) Chemistry and Materia Medica, 600 marks. No candidate is considered eligible who does not obtain one-third of the maximum marks in each of the compulsory subjects. Candidates may be examined in the following voluntary subjects: Zoology, 300 marks; Botany, 300 marks; Physics, 300 marks; Geology and Physical Geography, 300 marks (no candidate will be allowed to present himself for examination in more than two of these subjects); French and German (200 each), 400 marks. A number less than one-third of the marks obtainable in each of these voluntary subjects will not be allowed to count in favour of a candidate who has qualified in the compulsory subjects. Successful candidates immediately after passing the examination will receive commissions as surgeons in the Royal Navy and will undergo a course of practical instruction in Naval Hygiene, &c., at Haslar Hospital. Surgeons are promoted to be Staff Surgeons after twelve years from date of entry, provided they pass the requisite examination after completion of eight years' service from the date of entry; and Staff Surgeons to Fleet Surgeons after twenty years' service if recommended by the Director-General. Deputy-Inspectors-General are promoted by selection from the Fleet Surgeons, and Inspectors-General from the Deputy Inspectors-General having three years' foreign service, or four years' mixed, of which not less than two must have been abroad, or five years' home service in such appointments as preclude foreign service, provided they have not refused to go abroad when called upon to do so. Inspectors and Deputy Inspectors-General are retired compulsorily at sixty (except that if in any particular case the Lords Commissioners of the Admiralty may consider that the interests of the public service will be materially advanced by the further retention of an Inspector-General on the active list, the age for retirement of such Inspector-General may be extended to sixty-two) and other grades at fifty-five years of age, and all ranks at any time if an officer has not served for five years. In calculating service for retired pay time on half-pay will be taken as equivalent to one-third service on full-pay. All retired officers are liable, till the age of fifty-five, to serve in time of declared national emergency in a rank not lower than that held on retirement.

The following tables, showing the rates of pay and

Digitized by Google

half-pay of the three branches, will probably be acceptable to students who entertain any intention of entering the public service:—

ARMY.

Director-General of the Army, £1500 yearly; retired pay from £1125 to £830, according to length of service as Director-General.

Under Army Order 63 of May, 1897, officers of the Army Medical Staff attached to a militia unit during preliminary drill and training are entitled to an allowance in aid of mess at the rate of 4*s.* a day.

* Applies equally to Surgeon-Lieutenant-Colonel, Surgeon-Major, Surgeon-Captain, or Surgeon-Lieutenant, according to periods of service—i.e., ten, fifteen, or eighteen years.

An officer who, on voluntary retirement, has served for less than three years in the rank from which he retires is only entitled to the gratuity or retired pay assigned to the next lower rank.

† Half-pay is also applicable to officers having less than twenty years' service, as follows:—

Surg.-Lieut.-Col., Surg.-Major, Surg.-Capt., or Surg.-Lieut.:

	Daily.
Under 5 years' service	£0 6 0
After 5 ,, ,, ...	0 8 0

Inspector-General	2 15 0	1 18		

The half-pay, retired pay, and gratuities on retirement are liable o reduction in cases of misconduct.

The hospital allowances for Medical Officers at home and abroad, in lieu of provisions for themselves and servants and for fuel and light, are as follows:—

Rank.	At home.	Abroad.
	£	£
Inspector-Generals of Hospitals	85	130
Deputy Inspector-Generals	67	112
Fleet Surgeons and Staff Surgeons	53	112
Surgeons	39	108

Medical officers serving afloat receive an allowance of 1*s.* 6*d.* a day in lieu of provisions, fuel, and lights, as laid down in the Queen's Regulations.

The allowance of 5*s.* a day, in addition to full pay, at present granted to the Fleet Surgeon of a flag-ship bearing the flag of a Commander-in-Chief on a foreign station, will be given to the senior medical officer of such ship, being a Fleet or Staff Surgeon; and an allowance of 2*s.* 6*d.* a day to the senior medical officer, being a Fleet or Staff Surgeon, of the ship of a Commodore or of a senior officer commanding a foreign station.

Candidates will do well to notice that the regulations issued to applicants do not put any limit on the amount of half-pay service which they may be compelled to undergo.

‡ If the health of a surgeon breaks down before he completes eight years' service, even if his disability be contracted in the service or be due to climatic causes, he is liable to be at once placed on the retired list, receiving a gratuity at the rate of £125 for each year of completed service.

INDIAN MEDICAL SERVICE.§

The rate of pay drawn by Surgeon-Lieutenants from the date of passing the final examination at the Army Medical School until arrival in India is 10*s.* a day.

Pay at the above rate is issued in this country up to the date of embarkation, and an advance of two months' pay at the same rate is also made prior to embarkation, which is adjusted in India.

The following are the rates of "Indian pay and allowances" which will be drawn by officers hereafter appointed to the Indian Medical Service:—

Rank.	Years' service.	Indian pay and allowance per Mensem.	
		When not holding an appointment carrying higher pay.	
		Rs. a. p.	
Brigade-Surgeon-Lieutenant-Colonel		900 0 0	
Surgeon-Lieutenant-Colonel	25 and over	888 12 0	
Surgeon Lieutenant-Colonel	20 ,,	852 8 7	
Surgeon-Major	15 ,,	677 6 11	
,, ,,	12 ,,	640 14 6	
		A. When not receiving any staff allowance.	B. When receiving staff allowance in addition.
		Rs. a. p.	Rs. a. p.
Surgeon-Captain ..	10 ,,	500 0 0	450 0 0
,, ,, ..	5 ,,	450 0 0	400 0 0
Surgeon-Captain and Surgeon-Lieutenant	under 5	350 0 0	300 0 0

On first appointment they will only come into receipt of "Indian pay and allowances" from the date of their arrival in India.

Officers holding the principal administrative appointments and substantive military charges of the Indian Medical Service receive at present the following consolidated salaries:—

	Rs. per Mensem.
Surgeon-Major-General, Bengal ..	2700
,, ,, ,, Madras ..	2500
,, ,, ,, Bombay ..	2500
Surgeon-Colonel .. .. from .. to ..	2250 to 1800
Brigade-Surgeon-Lieutenant-Colonel in substantive charge of a native regiment	1100 with Rs. 90 horse allowance in cavalry regiments.
Surgeon-Lieutenant-Colonel in substantive charge of a native regiment	1000 with Rs. 90 horse allowance in cavalry regiments.
Surgeon-Major in substantive charge of ditto	800 with Rs. 90 ditto.
Surgeon-Captain above 5 years' full-pay service in substantive charge of a native regiment	600 with Rs. 60 ditto.
Surgeon-Captain or Surgeon-Lieutenant under 5 years' ditto in substantive charge of a native regiment	450 with Rs. 60 ditto.

The salaries of other substantive medical appointments in the Civil and Military Departments are consolidated and vary from Rs. 1800 to Rs. 400 per mensem.

Digitized by Google

Qualified officers of the Medical Service are also eligible for appointments in the Assay Department. The salaries of these appointments are from Rs. 600 to Rs. 2250 per mensem.

Officers are required to perform two years' regimental duty in India before they can be considered eligible for civil employment.

RETIRING PENSIONS AND HALF-PAY.

Officers of the Indian Medical Service will be allowed to retire on the following scale of pension, on completion of the required periods of service:—

After 30 years' service for pension	£700 per annum + £350 after 5 years' active employment in India as a Surgeon-Major-General, or + £250 per annum after 5 years' active employment as a Surgeon-Colonel.
,, 25 ,, ,, ,,	£500 per annum.
,, 20 ,, ,, ,,	£365 ,,
,, 17 ,, ,, ,,	£292 ,,

Officers not entitled to pension, when placed on temporary or permanent half-pay will be granted the British rate of half-pay of their military rank, as under:—

Rank.	Rates of Half-pay.	
	Per diem.	Per annum.
	s. d.	£ s. d.
Brigade-Surgeon-Lieutenant-Colonel ..	} 11 0	200 15 0
Surgeon-Lieutenant-Colonel		
Surgeon-Major	9 6	173 7 6
Surgeon-Captain	7 0	127 15 0
Surgeon-Lieutenant	8 0	54 15 0

INVALID PENSIONS.

An officer who has become incapacitated for further service in India on account of unfitness caused by duty may, after he has been two years on temporary half pay, be granted an Invalid Pension on the following scale:—

	Per annum.
After 16 years' pension service	£272
,, 15 ,, ,, ,, ...	252
,, 14 ,, ,, ,, ...	232
,, 13 ,, ,, ,, ...	212
,, 12 ,, ,, ,, ...	192

§ No staff or regimental allowance can be drawn until the lower standard examination in Hindustani has been passed. As many surgeon-lieutenants have been sent to the frontier immediately on arriving in India, they have found it impossible to study and pass this examination, and have consequently been doing regimental and other work for Rs. 317 8a. a month. Lately a concession has been granted to medical officers so situated on the frontier, but the rule is still most illiberal and requires alteration.

‖ Officers cannot retire *in India* on half-pay (No. 45, Feb. 28th, 1865).

WOUND PENSIONS.

Officers are entitled to the same allowances on account of wounds and injuries received in action as are granted to combatant officers of Her Majesty's Indian Military Forces holding the corresponding military rank.

FAMILY PENSIONS.

The claims to pension of widows and families of officers are treated under the provisions of such Royal Warrant regulating the grant of pensions to the widows and families of British officers as may be in force at the time being.

The widows and families of officers are also entitled to pensions under the Indian Service Family Pension Regulations, for the benefits of which all officers must, as a condition of their appointment, subscribe from the date of their arrival in India.

METROPOLITAN MEDICAL SCHOOLS.[1]

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The clinical practice of the hospital comprises a service of 750 beds, of which 676 are for patients in the hospital at Smithfield and 75 for convalescent patients at Swanley. Ten house physicians and ten house surgeons are appointed annually. During their first six months of office they act as "junior" house physicians and house surgeons and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons and are provided with rooms by the hospital authorities and receive £80 a year as salary. A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anæsthetists are appointed annually, and receive salaries of £120 and £100 respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Two assistant electricians are appointed every six months. The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in-patients and to the out-patients, and the dressers in the special departments are chosen from the diligent students. All the appointments are now free.

A college is attached to the hospital, in which students can reside, subject to the college regulations.

The Medical School Buildings include three large lecture theatres, a large dissecting room, a spacious library (containing 13,000 volumes), a well-appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy. There are laboratories for chemistry, physiology, pathology, pharmacology, public health, and biology, giving ample accommodation in every department.

A recreation ground of ten acres has been purchased by the school committee at Winchmore-hill for the use of the Students' Amalgamated Clubs, and all students are expected to become members.

Instruction in Preliminary Science is given to University of London students in chemistry, biology, and physics throughout the year.

Laboratory Instruction for the D.P.H. is provided during the winter and summer sessions, and elementary instruction in Bacteriology is also given throughout the year.

CHARING-CROSS HOSPITAL AND COLLEGE.—Total fees, 110 guineas if paid in a single sum on entry, or 121 guineas if paid in five instalments; the sons of Registered Medical Practitioners pay 100 guineas in one sum or 110 guineas in five sums; for Dental students, 54 guineas, or 60 guineas in two equal instalments. General students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery and to the practice of the Royal Westminster Ophthalmic Hospital. They alone are entitled to compete for the Scholarships, Gold Medal, and Pereira Prize.

Classes for the Preliminary Scientific Examination of the University of London are held at this Medical School. The fee for the whole course, which begins in October, is 15 guineas. There are also special classes for the practical work for the Department of Public Health and a course in the subject of Diseases of tropical climates.

ST. GEORGE'S HOSPITAL.—Students may become Perpetual Pupils by payment of £150 on entering, or of £160 in four annual instalments. Perpetual pupils are entitled to perpetual admission to lectures and demonstrations as well as to the entire medical and surgical practice of the hospital; they may compete for all prizes and exhibitions, may become clinical clerks during six months and dressers during another six months, or longer if required, without fee, may attend midwifery practice, and may compete for all hospital and school appointments without extra charge. Four house surgeoncies and four house physiciancies, and the salaried offices of obstetric assistant, senior and junior anæsthetists, medical registrars (2), surgical registrar, curator and assistant curator of the Museum, besides demonstratorships and a number of junior hospital appointments, are open to perpetual pupils. Students not being perpetual pupils are admitted to lectures, demonstrations, and hospital practice on payment of £50 annually for two years and £20 annually for succeeding years. Such students may become Perpetual in their third year if they wish and if their conduct has been satisfactory.

GUY'S HOSPITAL.—House physicians, house surgeons, assistant house physicians, and assistant house surgeons, obstetric residents, gynæcological assistants, clinical assistants, clerks to anæsthetists, surgeons' and assistant surgeons' dressers, surgical ward clerks, clinical clerks, post-mortem clerks, extern obstetric attendants, and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the medical staff, according to merit and without extra payment. The house physicians, of whom there are four, hold office for six months each. The assistant house physicians, who hold office for three months, attend in the out-patient department four afternoons in the week, and see all the cases not seen by the assistant physician of the day. The house physicians have the care of the patients in the medical wards, and attend to all emergencies arising in the absence of the physicians. They

FEES for School and Hospital Medical and Surgical Practice.	£135, or in four instalments: 1st year, £56; 2nd year, £40; 3rd year, £30; 4th year, £10.		

are provided with board and lodging in the college free of expense. The house surgeons, of whom there are four, hold office for six months each, and are provided with board and lodging in the college free of expense. The Surgical Casualty Department is in charge of two assistant house surgeons. The surgeons' dressers are selected from those students who have completed their third winter session, and have been most diligent in the junior appointments. They hold office for three or six months. Six are attached to each surgeon, and during their weeks of special duty they are provided with board and lodging in the hospital free of expense. The obstetric residents, two in number, are provided with board and lodging in the college free of expense.

Higher Examinations.—Classes are held throughout the year for the Preliminary Scientific Examination of the University of London; and special courses of instruction in anatomy and physiology are provided for students preparing for the Primary Fellowship examination and the intermediate M.B. examinations of Oxford, Cambridge and London. Two courses of Laboratory instruction for candidates for a Diploma in Public Health are given annually.

The College.—The College stands upon a site fronting the east gate of the hospital, and is connected with it by a subway. The building serves as a Residential College for Students, and at the same time provides accommodation for the Students' Club. The Clubs' Union ground is less than twenty-five minutes' journey from the Hospital. The new school buildings are now open.

KING'S COLLEGE.—Resident medical officers have rooms at the hospital and commons free; they are selected by examination and hold their appointment for six months. There are two physician's assistants, two physician accoucheur assistants, and three house surgeons. Sambrooke registrarships, value £50 per annum, are tenable for two years. Clinical assistants senior and junior of the special departments—ophthalmic, ear, and throat. Senior dressers and dressers, clinical clerks, assistant demonstrators of anatomy and physiology, and prosectors are re-elected by examination, and in consideration of their former work in the medical school as matriculated students. Classes for the science subjects required by the University of London are held by the Professors of the Science Faculty of King's College, and students avail themselves of their laboratories.

Laboratories.—Bacteriology, State Medicine, Pathology, and Neuropathology have special laboratories.

Resident Chambers.—There are chambers at King's College available for a limited number of students; rent, including dinner during terms, £50 to £60 a year.

Athletic Club.—All students are entitled to the privileges of the Athletic Club, which manages a large recreation ground of the College at Wormwood Scrubbs.

LONDON HOSPITAL AND COLLEGE.—The hospital, which is the largest in Great Britain, contains nearly 800 beds. Last year the number of in-patients was 11,337, out-patients 158 002, and the number of accidents 14,625.

Special classes are held throughout the year for the Preliminary Scientific and Intermediate M B. Examinations of the University of London and for the Primary and Pass Examinations for the Fellowship of the Royal College of Surgeons. Special entries can also be made for Medical and Surgical Practice, the Operative Surgery classes, &c.

Instruction is given throughout the year in all the details required for the Diploma in Public Health.

In addition to the regular courses of lectures there will be given during the summer session a course of lectures on Clinical Surgery by Mr. Jonathan Hutchinson, F.R.S., Emeritus Professor of Clinical Surgery.

ST. MARY'S HOSPITAL.—There are three house physicians and three house surgeons, each appointed for six months, and two obstetric officers, each appointed for six months. They board free of expense in the hospital, except that the obstetric officer resides outside the hospital for the first three months. These appointments are awarded after competition, without additional fee. Two demonstrators of anatomy are appointed annually, with a salary of £70 each; and a demonstrator of physiology, at £100 a year. All these officers are eligible for re-election. Two prosectors of anatomy, two or more assistant demonstrators of anatomy, physiology, chemistry, biology and pathology are appointed annually, and receive an honorarium of £5 each. All students are required to perform the duties of clinical clerk and dresser during the last two years of their curriculum. Students of the third year and of subsequent years are also appointed as clerks and dressers to assist the physicians and surgeons in charge of the out-patients. The hospital contains 281 beds. Two wards are appropriated to the Diseases of Children, and one to those of Women; beds are also provided for Ophthalmic, Aural, and Cutaneous cases. There is an out-patient department for Diseases of Children. Special assistance is

Digitized by Google

given to intending candidates for the final examinations of the Medical, Surgical, and Obstetric tutors.

Clarence Memorial Wing.—The foundation-stone of this important addition to the hospital was laid by H.R.H. the Prince of Wales and the new out-patient department in it will be completed and opened in October of this year. At the same time the out-patients' rooms will be given up to the school to make additional class-rooms, with a new museum and laboratories. The new wing will present features of the greatest interest in the bearing it must necessarily have upon the future efficiency of the Medical School. The Lying-in Wards will be more especially noteworthy as the first established within a metropolitan general hospital. The prospectus may be had on application to Mr. F. H. Madden, the School Secretary, to Mr. G. P. Field, the Dean, or Dr. A. P. Luff, the Sub-Dean.

A residence for students, 33 and 35, Westbourne-terrace, W., in connexion with the hospital, is under the charge of a warden, Mr. H. S. Collier, F.R.C.S., who is prepared to receive applications from students desiring to enter upon residence during the ensuing session. Terms: £75 for the academical year.

Qualified medical men are admitted to unlimited attendance on hospital practice at a fee of £15 15*s.*

MIDDLESEX HOSPITAL.—The hospital contains 320 beds. There is a special department for patients suffering from cancer, consisting of four wards, containing thirty-four beds; here cancer patients are received and attended for a period limited only by the duration of their disease.

Hospital Appointments.—Clinical Clerkships and Dresserships in all departments are allotted to students without any extra fee. Eighteen Resident Appointments are annually filled from the pupils of the hospital, each appointment extending over six months.

The Curriculum is designed to meet the requirements of the Royal Colleges of Physicians and Surgeons and of the Universities of London, Cambridge, &c. Special Classes are held to prepare students for the Preliminary Scientific M.B. (Lond.) Examination and for the Primary Examination for the diploma of F.R.C.S. Eng.

The new school buildings now in progress will provide a much larger dissecting-room, a room for operative surgery, a complete physiological department, spacious pathological and bacteriological laboratories, and extended facilities for the teaching of Chemistry, Physics, Biology, &c.

A Residential College to accommodate about thirty students adjoins the hospital. The charge for residence is £10 10*s.* and £8 8*s.* per term, according to the position of the room. Breakfast, luncheon, and dinner are supplied in the College Hall at a very moderate charge.

Fees.—The Composition Fee for the entire curriculum is 120 guineas, or 130 guineas if paid in three instalments. The fee for the Dental Curriculum is 54 guineas, or 60 guineas if paid in two instalments. Students from the Universities and students who have passed the London Preliminary Scientific M.B. Examination are received on special terms.

ST. THOMAS'S HOSPITAL.—The composition fee to Hospital Practice and Lectures may be paid in the following ways:—1. £150 on entrance in one sum. 2. £157 10*s.* in instalments: (*a*) by two payments, £85 on entrance and £72 10*s.* at the beginning of the second year; (*b*) by three payments, £75 at the beginning of the first year, £50 at the beginning of the second year, and £32 10*s.* at the beginning of the third year; and (*c*) by four payments, £65 at the beginning of the first year, £50 at the beginning of the second year, £30 at the beginning of the third year, and £12 10*s.* at the beginning of the fourth year. Gentlemen entering at St. Thomas's for Lectures and Hospital Practice of the second and subsequent years pay £130 on entrance, or three instalments of £52 10*s.*, £42, and £42. Students entering for Lectures and Hospital Practice of third and subsequent years pay a composition fee of £80, or £52 10*s.* on entrance and £31 10*s.* one year subsequently. The fee for attendance on the general subjects required of students in Dental Surgery is for the two years £65, or, by instalments, £55 for the first year and £15 for the second year. If certificates for Dental Practice are also required the special fee for that subject has to be paid. Qualified practitioners are admitted on payment of a fee of 15 guineas.

UNIVERSITY COLLEGE, LONDON.—*Composition fees.*—1. For the entire medical education required by the Examining Board in England and the Society of Apothecaries, 135 guineas, if paid in one sum at the commencement of the course; 140 guineas if paid by instalments, as follows—first year, 65 guineas; second year, 50 guineas; third year, 25 guineas. 2. For those students who do not require to attend Chemistry, Pharmacy, and Elementary Biology at a medical school (under the regulations of the Examining Board in England) the fee will be—117 guineas, if paid in one sum; 122 guineas, if paid by instalments, as follows—first year, 55 guineas; second year, 40 guineas; third year, 27 guineas. 3. For the whole course of instruction for the Intermediate Examination in Medicine of the University of London, 55 guineas (paid in one sum). 4. For the course of instruction for the Final M.B. Examination of the University of London, 76 guineas, if paid in one sum; 78 guineas, if paid by instalments, as follows—first year, 45 guineas; second year, 33 guineas. 5. Composition fee for Dental Students, 65 guineas. 6. Composition fee for the whole course of instruction for the Preliminary Scientific (M.B.) Examination of the University of London, 35 guineas.

Eight house physicians, six house surgeons, four senior and eight junior obstetric assistants are selected annually by examination from among the senior students. The house physicians and house surgeons reside in the hospital for a period of six months, and the senior obstetric assistants for three months, receiving free board and lodging.

Several professors and other gentlemen connected with the College receive students to reside with them; and in the office of the College there is kept a register of persons unconnected with the College who receive boarders into their families; among these are several medical gentlemen and clergymen.

WESTMINSTER HOSPITAL.—The hospital contains upwards of 200 beds. There are separate departments for Diseases of the Eye, Ear, Skin, Teeth, and Throat, for Orthopædics, and for Diseases of Women, and a special ward for Children. The Anatomical Museum is open to the students. There are also Pathological and Materia Medica Museums.

A curator of the museum and a pathologist, with salaries of £40 and £50 respectively, and a medical and surgical registrar, each with a salary of £40, are appointed annually. Two house physicians, two house surgeons, and a resident obstetric assistant are appointed for six months after examination, and are provided with rooms and commons; also two assistant house surgeons with commons only. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among qualified students of the hospital.

Preliminary Scientific.—Special classes are held in the subjects of this examination—Chemistry, Dr. Hake; Physics, Mr. Somerville; Biology, Dr. Tims. The extra fee to a general student is 12 guineas.

Intermediate M.B.—Advanced Physiology and Histology, Dr. Gossage; Advanced Anatomy, Dr. Tims and Mr. Tubby; Organic Chemistry, Dr. Hake; Materia Medica, Dr. Murrell.

D.P.H.—The course of Laboratory Instruction may now be taken. Physics, Mr. Somerville; Chemistry, Dr. Hake; Bacteriology, Dr. Blaxall. Fee 12 guineas.

Bacteriology.—A course in General Bacteriology is given by Dr. Blaxall. Fee £5 5*s.*

LONDON SCHOOL OF MEDICINE FOR WOMEN, 30, Handel-street, Brunswick-square, W.C.—The winter session of this School, which is in connexion with the Royal Free Hospital, Gray's-inn-road, will begin on Oct. 1st, 1897, and will end on March 31st, 1898. The summer session will begin on May 2nd, and will end on July 30th, 1898. No student will be admitted to the study of Medicine who has not completed her eighteenth year. The admission of students rests exclusively with the Executive Council.

In addition to the list of Scholarships tabulated in another column three Evans Prizes of £3 3*s.*, £2 2*s.*, and £1 1*s.* are given in the Midwifery Class to enable students to take operative midwifery. There is also a small fund from which assistance can occasionally be given to students and to graduates who specially require pecuniary help to obtain additional experience in operative midwifery, &c. The Evans Prize for Operative Midwifery, value £5 5*s.*, will be offered at the end of the winter session, 1898. Two Singleton prizes are offered to students of the School who

Digitized by Google

have held posts at the New Hospital for Women. Honoraria from the Boyce Memorial Fund are given to the senior assistant anæsthetist at the Royal Free Hospital. Prizes and Certificates of Honour are awarded in each class at the end of the session. Secretary, fresh appointment shortly.

METROPOLITAN ANCILLARY SCHOOLS AND HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

BETHLEM HOSPITAL.—This hospital is open for the admission of two Resident Clinical Assistants who have recently obtained their diplomas to practise Medicine and Surgery. They will be permitted to reside in the hospital for a term generally not exceeding six months, and will be provided with such apartments, rations, and attendance as the Committee shall consider reasonable. They will be under the direction of the Resident Physician, and will be elected by the Committee from candidates whose testimonials appear to be most satisfactory. The students of certain specified London Medical Schools receive Clinical Instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Lectures are also given in connexion with the London Post-graduate Course.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Four House Physicians reside in the hospital for a period of six months. Pupils are admitted to the practice of the hospital: terms, £1 1*s.* for one month; six months, £5 5*s.*; perpetual, £5 5*s.* Lectures and Clinical Demonstrations are given throughout the year by members of the medical staff. The next course will commence in October. Clinical Assistants are appointed to the Assistant Physician in the out-patient department and Clinical Clerks to the Physician in the wards. The hospital has been recognised by the Conjoint Board for England as a place where six months of the fifth year may be spent in clinical work. The medical practice of the hospital is also recognised by the University of London, the Apothecaries' Society, and the Army and Navy and Indian Medical Boards. The hospital contains 321 beds in the two buildings.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park.—During the past year 938 in-patients have been admitted, and the large number of 30,532 cases have been treated since the opening of the wards in 1855. The number of out-patients treated during 1896 was 17,451 and 569,329 since the commencement of the institution in 1848. Information as to medical instruction can be obtained on application to the Secretary of the Clinical Sub-committee at the hospital. Consulting Physician: Dr. E. L. Birkett. Consulting Surgeon: The Rt. Hon. Lord Lister, P.R.S. Physicians: Drs. J. C. Thorowgood, Eustace Smith, G. A. Heron, Vincent D. Harris, E. Clifford Beale, and Harrington Sainsbury. Surgeon: Mr. J. F. C. H. Macready, F.R.C.S. Assistant Physicians: Dr. T. Glover Lyon, Sir Hugh R. Beevor, Bart., and Drs. W. J. Hadley, E. H. Colbeck, Arnold Chaplin, and Hugh Walsham.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's-inn-road.—The hospital contains accommodation for seventeen in-patients, and has a very extensive out-patient department, which is open to all medical practitioners and students for the purpose of clinical demonstration and instruction during the hours of the surgeons' visits. During the past year 7200 out-patients and 301 in-patients were treated. Fee for three months' attendance, 3 guineas; for six months, 5 guineas. A course of lectures on the special diseases treated at this hospital is delivered during the winter months by members of the staff. As an evidence of the interest excited by these lectures, it may be mentioned that last year there were over a thousand attendances at the series with an average of eighty at each lecture. The date of these lectures is announced in the medical journals prior to their commencement. They are free to qualified practitioners and advanced students of medicine. Considerable attention is given to scientific work, particularly with regard to Bacteriology of the ear and respiratory passages, for which a special department has been inaugurated. Consulting Surgeon: Mr. Thomas Nunn. Surgeons: Mr. Lennox Browne, Dr. Arthur Orwin, Dr. Dundas Grant, and Mr. Percy Jakins. Assistant Surgeons: Mr. Wyatt Wingrave and Dr. Holloway. Bacteriologist: Mr. St. George Reid. Dental Surgeon: Mr. George Wallis. Defects of Speech: Mr. William Van Praagh. In addition the following appointments are open to qualified members of the profession:—Three Assistant Registrars and Anæsthetists, tenable for twelve months; and twelve Clinical Assistants, tenable for six months. Secretary: Mr. Richard Kershaw.

HOSPITAL FOR WOMEN, Soho-square, W.—In connexion with this institution there has been for some years a well-organised Clinical Department. This has been enlarged under the title of the London School of Gynæcology. To meet the want increasingly felt by medical men of an accurate knowledge of the ordinary diseases of women gentlemen are appointed every three months to act as clinical assistants to the physicians and surgeons seeing out- and in-door patients. The appointments are nominally "open to qualified medical men and to students of medicine after their fourth year," but in the selection of candidates preference is naturally given to gentlemen already engaged in practice. The large number of out-patients affords exceptional opportunities for practical instruction in the use of gynæcological instruments and for the study of diseases peculiar to women. Clinical instruction is also given in the theatre and the wards. Fee for the three months' course, £8 8*s.* Any further information can be obtained by letter addressed to the Dean at the hospital.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road. (Established 1814.)—This hospital has been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients. Expenditure for 1896, £7459; income (including legacies, £2803), £10,108. The attendance of out-patients averages 24,000 annually.

ROYAL EAR HOSPITAL Soho. (Founded 1816.)—Courses of six weeks' duration in Diseases of the Ear and Nose are given by the members of the staff throughout the teaching year. Students can attend one or more surgeons, the fee for each surgeon's course being one guinea. The teaching is of a practical character, and the number of students is limited. The next series of classes will commence on Oct. 1st. For information address the Hon. Sec. of the Medical Board.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.—Consulting Surgeon: Mr. W. Adams. Physicians: Drs. R. Burnet, E. C. Beale, C. E. Beevor, H. W. Syers, James Galloway, and A. Morison. Obstetric Physicians: Dr. L. Remfry and Dr. Blacker. Surgeons: Messrs. J. Macready, C. B. Lockwood, H. Allingham, P. T. B. Beale, and G. B. M. White. Ophthalmic Surgeon: A. S. Morton. Throat Aural Surgeon: Mr. W. R. H. Stewart. Skin Department: Dr. Cook. Dental Surgeon: Mr. P. Trier Harris. This hospital is now recognised by the Examining Board in England by the Royal Colleges of Physicians and Surgeons as a place of study during the fifth year of the Medical Curriculum. The hospital contains 155 beds, of which 100 are at present occupied. The large rectangular and circular wards, each of which contains 20 beds, the operation theatre, out-patient, general and special, and the pathological departments, have all been erected since 1887. They are specially designed with a view of offering the greatest facilities for clinical work, and contain all the most recent and approved hygienic and antiseptic requirements for the proper care of the sick and for the treatment of disease. Medical practitioners are cordially invited to see the general and special practice of the hospital. Clinical assistants (qualified), clinical clerks, and pathological clerks are appointed in the general and special departments and may receive certificates at the end of their terms of office. Further particulars from Peyton T. B. Beale, F.R.C.S., Hon. Secretary Medical Committee, 61, Grosvenor-street, W.

NEW HOSPITAL FOR WOMEN, 144, Euston-road, N.W.—Physicians for In-patients: Miss Cock, M.D., and Miss Walker, M.D. Surgeons for In-patients: Mrs. Scharlieb, M.D., M.S., and Mrs. Boyd, M.D. Physicians and Surgeons for Out-patients: Miss Webb, M.B., Miss Macdonald, M.B., and Miss Aldrich Blake, M.D., M.S. Ophthalmic Surgeon: Miss Ellaby, M.D. Assistant Physicians for Out-patients: Miss Chadburn, M.B., Mrs. Wilks, M.D., and Miss Caine, M.B. Physician for Maternity Department: Miss Harris, M.B. Anæsthetist: Mrs. Keith, L.R.C.P. A considerable number of the students hold posts in the New Hospital under the visiting staff, and in return for much valued clinical teaching they do the work assigned to students in the wards of a general hospital. Secretary: Miss M. M. Bagster.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W. (Established 1873.)—Physicians: Dr. Wilde, Dr. J. J. Ridge, and Dr. Fenwick. Surgeon: Dr. W. J. Collins, F.R.C.S.

Digitized by Google

Dental Surgeon: Mr. A. Alexander. The hospital contains 110 beds. The in-patients in 1896 were 1157, and the out-patients and casualties numbered 17,392 new cases. The medical and surgical practice of the hospital is open to students and practitioners. Special departments for Ophthalmology and Gynæcology. Operations: Mondays and Thursdays, 3.30 P.M. Classes will be held during the winter and summer sessions for students preparing for the final examinations at the Colleges and the Universities. Appointments, vacancies for which are advertised in the medical journals: Registrar and Pathologist; Resident Medical Officer and Assistant Resident Medical Officer. For particulars as to hospital practice and classes apply at the hospital to Dr. W. J. Collins.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Albany Memorial), Queen-square, Bloomsbury.—The hospital, with the Finchley branch, contains 200 beds and cots. The physicians attend every Monday, Tuesday, Wednesday, and Friday at 2 P.M. In- and out-patient practice and electrical-room treatment at that hour. Physicians: Drs. Ramskill, Hughlings Jackson, Buzzard, Bastian, and Gowers. Physicians for Out-patients: Drs. D. Ferrier, Ormerod, Beevor, and Tooth. Assistant Physicians: Drs. James Taylor and W. S. Colman. Surgeons: Messrs. Victor Horsley and C. A. Ballance. Ophthalmic Surgeons: Messrs. R. Brudenell Carter and Marcus Gunn. Aural Surgeon: Mr. A. E. Cumberbatch. Laryngologist: Dr. Felix Semon. Anæsthetist: Dr. Dudley Buxton. Pathologist: J. Risien Russell. Registrar: A. J. Whiting. House Physicians: Drs. Stewart and Collier. The hospital has been recognised by the conjoint Board for England as a place where part of the fifth year may be devoted to clinical work. All communications concerning clinical appointments, lectures, and hospital practice should be addressed to the Secretary and Director at the hospital.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL AND MIDWIFERY TRAINING SCHOOL, Marylebone-road, N.W.—Consulting Physician: Dr. George B. Brodie. Consulting Surgeons: Mr. H. Lee and Sir William MacCormac. Physicians to In-patients: Dr. W. C. Grigg and Dr. W. S. A. Griffith. Physicians to Out-patients: Dr. W. Rivers Pollock and Dr. W. J. Gow. This hospital, which has been recently enlarged, receives over 1100 patients annually, besides having a large out-patient department. Medical pupils are received at all times of the year. Pupils have unusual opportunities of seeing obstetric complications and operative midwifery, on account of the very large number of primiparous cases — nearly three-fourths of the total admissions. Clinical instruction is given on the more important cases which present themselves. Certificates of attendance at this hospital are recognised by all Universities, Colleges, and licensing bodies. Pupil midwives and monthly nurses are received and specially trained. Fees: Medical Students, £8 8*s*. for four weeks; Qualified Medical Practitioners £8 8*s*. for four weeks. Pupil Midwives, £26 5*s*. for three months (including board and lodging); Pupil Nurses, £15 15*s*. for twelve weeks (including board and lodging). There is a residence for students and qualified practitioners within fifty yards of the hospital, with which it is in telephonic communication. Terms for residence and partial board one guinea per week. For further particulars application should be made to Mr. Arthur Watts, Secretary, at the hospital.

SEAMEN'S HOSPITAL SOCIETY, Dreadnought Hospital, Greenwich, S.E. (235 beds). Royal Victoria and Albert Dock Hospital, E. (18 beds). Dispensaries: East India Dock-road, E., and Gravesend.—This institution is established for the relief of seamen of all nations. Casualties are received at all hours. Apartments are provided in the house of the Principal Medical Officer for students, and students are allowed to attend the general practice at either of the hospitals. Facilities are given for the study of Eastern diseases. Honorary Consulting Physicians: Dr. Robert Barnes and Sir Richard Quain, Bart., F.R.C.P. Visiting Physicians: Dr. John Curnow and Dr. John Anderson, C.I.E. Visiting Physician to the Royal Victoria and Albert Dock Hospital: Dr. Patrick Manson. Honorary Consulting Surgeon: Mr. J. N. Davies-Colley. Visiting Surgeon: Mr. G. Robertson Turner. Visiting Surgeon to the Royal Victoria and Albert Dock Hospital: Mr. W. Turner. Principal Medical Officer: Mr. W. Johnson Smith. Ophthalmic Surgeon: Mr. D. S. Gunn. House Physician: Mr. A. E. Griffin. House Surgeon: Mr. D. E. Darbyshire. Branch Hospital:—House Surgeons: Mr. D C. Rees and Mr. J. R. Prior. Gravesend Dispensary:—Surgeon: Mr. C. E. Robbs. Secretary: Mr. P. Michelli.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C., contains 186 beds, divided into 88 medical, 73 surgical, and 25 for special and infectious cases, besides 52 beds at the convalescent branch, Highgate. The hospital having been recognised by the conjoint Board for England as a place where, under the new curriculum, six months of the fifth year may be spent in clinical work, the practice is arranged to meet this need and is open to students who have completed four years of medical study and also to qualified medical men. Appointments are made every three months to six medical clerkships and six surgical clerkships, which are open to students of the hospital. Lectures or demonstrations are given once or twice every week during both winter and summer sessions. The sessions are of ten weeks' duration, and begin in October, January, and March. Fees for hospital practice, three months, 2 guineas; perpetual, 3 guineas. Prospectuses and further information will be forwarded on application to the Secretary, Mr. Adrian Hope, at the hospital.

ROYAL LONDON OPHTHALMIC HOSPITAL, Moorfields.—The hospital, founded in 1804 and considerably enlarged in 1876, now contains 100 beds for patients, which were occupied during last year by 2006 persons. The out-patients are yearly 26,000; attendances, 130,374 in 1896. Operations are performed daily from 10 A.M. to 1 P.M., and three surgeons attend on each day. Students are admitted to the practice. Fee for six months, £3 3*s*; perpetual, £5 5*s*. Classes, demonstrations, and lectures are periodically given, to which perpetual students are admitted free. Students of the hospital are eligible for the office of house surgeons, or may be appointed clinical and junior assistants. The Secretary, Mr. Robert J. Newstead, will furnish further information, as may be desired.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand.—The hospital contains 35 beds; and the patients, who number 11,000 annually, are seen at 1 P.M., and operations performed daily at 2 P.M. The following are the days of attendance of the surgeons: Mr. Hartridge and Mr. Dodd, Mondays and Thursdays; Mr. Frost and Mr. D. Gunn, Tuesdays and Fridays; and Mr. Juler and Mr. Griffith, Wednesdays and Saturdays. The practice of the hospital is open to practitioners and students. Fees for six months, £3 3*s*.; perpetual, £5 5*s*. Students of the hospital are eligible for the post of house surgeon and clinical assistant. Special demonstrations and lectures will be given during the session, commencing in October; for details see weekly journals. Clinical Assistants (who must be duly qualified) to the Surgeons are appointed for periods of six months. Secretary: Mr. T. Beattie-Campbell.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C — The out-patient practice is open to the medical profession at the following times: Every day, except Friday, from 2 to 4 P.M., and Thursday mornings from 10.30 to noon. Specially selected Clinical Demonstrations, also demonstrations on the different diseases presenting themselves in the out-patient department, followed by Lectures, will also be given.

ST. PETER'S HOSPITAL FOR STONE AND URINARY DISEASES, Henrietta-street, Covent-garden. Established 1860. New Hospital built, 1882.—Honorary Surgeons: Mr. F. R. Heycock, Mr. F. Swinford Edwards, Mr. E. Hurry Fenwick, and Mr. Reginald Harrison. Surgeon to the Out-patients, Mr. P. J. Freyer. Pathologist: Mr. E. Hurry Fenwick. The hospital contains 24 beds and 2 private wards. Consultations are held and operations are performed each Wednesday and Friday at 2 P.M. Medical practitioners and students are invited to the clinical instructions which are given in the wards and out-patient department daily, and to the operations in the theatre on Wednesdays and Fridays at 2 P.M. Average beds occupied daily, 19; average out-patients seen daily, 100.

BRITISH INSTITUTE OF PREVENTIVE MEDICINE (with which is amalgamated the COLLEGE OF STATE MEDICINE).—The winter session commences on Oct. 1st and the summer session on May 1st. The laboratories are open daily from ten to five o'clock for the purpose of instruction and original research work, which is under the supervision of Allan Macfadyen, M.D., B.Sc., assisted in the Bacteriological Department by R. T. Hewlett, M.D., M.R.C.P., and in the Chemical Department by Mr. A. G. R Foulerton, F.R.C.S., D.P.H. Camb. Bacteriology in relation to Medicine and Pathology (fee £5 5*s*.). Bacteriology in relation to Hygiene (£5 5*s*.). Biological Chemistry (fee £12 12*s*.). Principles of Hygiene (fee, six months, £15 15*s*.; three

Digitized by Google

months, £10 10s.). Every facility is given for original research, and there are departments for clinical investigation, the bacteriology of fermentation, a water laboratory, and a photo-micrographical department. Honorary secretary, Allan Macfadyen, M.D., B.Sc., 101, Great Russell-street, W.C.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—Physicians: Dr. Eustace Smith, Dr. Horatio B. Donkin, Dr. J. A. Coutts, and Dr. Dawson Williams. Surgeons: Mr. R. W. Parker and Mr. L. A. Dunn. Assistant Physicians: Dr. T. H. Arnold Chaplin, Dr. J. A. Hayward, Dr. Morley Fletcher, and Dr. E. Graham Little. Assistant Surgeon: Mr. H. B. Robinson. Resident Medical Officer: Dr. R. P. Cockburn. House Surgeon: Dr. A. B. Tucker. House Physician: Dr. M. S. Paterson. Secretary: Mr. Thomas Hayes. Lady Superintendent: Miss Adelaide Row. The hospital maintains 102 cots, and on an average 178 out-patients are seen daily. Clinical instruction is given by the physicians and surgeons to the hospital, which is recognised by the Conjoint Board for England as a school of medical teaching for students in the fifth year of the curriculum. All particulars may be obtained on application to the Secretary.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Consulting Physicians: Dr. W. S. Playfair, Dr. J. F. Goodhart, and Dr. Frederick Taylor. Physicians: Drs. Nestor Tirard and Frederick Willocks. Physicians to Out-patients: Drs. George Carpenter and W. Soltau Fenwick. Consulting Surgeons: Messrs. H. G. Howse and R. Clement Lucas. Surgeons: Messrs. G. H. Makins and F. S. Eve. Surgeons to Out-patients: Messrs. A. H. Tubby and F. C. Abbott. Dental Surgeon: Mr. R. Denison Pedley. Senior Resident Medical Officer: Mr. J. B. Christopherson. Junior Resident Medical Officer: Mr. O. K. Williamson.

VICTORIA HOSPITAL FOR CHILDREN, Chelsea, S.W.—The hospital contains 70 beds and has a large out-patient department (over 1000 weekly); the home at Broadstairs has 50 beds. Consulting Surgeon: Mr. Cowell. Physicians: Dr. Ridge Jones and Dr. Dawtrey Drewitt. Physicians to the Out-patients: Drs. Montague Murray, Walter Carr, Humphry D. Rolleston, and Raymond Crawfurd. Surgeons: Messrs. Pick and D'Arcy Power. Surgeons to the Out-patients: Messrs. Raymond Johnson and H. F. Waterhouse. Ophthalmic Surgeon: Mr. W. J. Holmes Spicer. Dental Surgeon: Mr. Percy Smith. Anæsthetists: Dr. Paul Frank Moline and Dr. C. J. Harrison. House Surgeon: Mr. H. B. Muir. House Physicians: Mr. Louis B. Hayne and Mr. Walter Allingham. Consulting Physician: Sir Wm. Broadbent, Bart. Secretary: Mr. A. Cameron Skinner. Out-patients are seen as under:—Medical and Surgical Cases: Daily, at 12.30 P.M., and every afternoon at 1.30 P.M. Dental Cases: Saturdays, at 9 A.M.

WEST LONDON HOSPITAL, Hammersmith-road, W.—This hospital has 97 beds at present in use. A new wing providing 80 other beds or thereabout is now complete, and will be opened as soon as possible. About 1700 in-patients and 32,000 out-patients, whose attendances number 75,000, are treated annually. There are appointments for two House Physicians and two House Surgeons, with board and residence, tenable for six months; also appointments for a limited number of Clinical Assistants. Physicians: Drs. D. W. C. Hood, F. G. D. Drewitt, and J. B. Ball. Physician for Diseases of Women: Dr. J. A. Mansell Moullin. Surgeons: Messrs. C. B. Keetley, F. Swinford Edwards, and S. Paget. Surgeon for Diseases of the Eye: Mr. B. J. Vernon. Assistant Physicians: Drs. Seymour Taylor, W. Hunter, W. A. Turner, and A. Whitfield. Assistant Physician for Diseases of Women: Dr. G. H. Drummond Robinson. Assistant Surgeons: Messrs. L. A. Bidwell, G. L. Cheatle, and W. McAdam Eccles. Assistant Surgeon for Diseases of the Eye: Mr. H. P. Dunn. Surgeon-Dentist: Mr. H. Lloyd Williams. Physician-in-Charge of Throat and Nose Department: Dr. J. B. Ball. Surgeon-in-Charge of Aural Department: Mr. S. Paget. Surgeon-in-Charge of Orthopædic Department: Mr. C. B. Keetley. Pathologist: Dr. W. A. Turner. Dermatologist: Dr. P. S. Abraham. Administrators of Anæsthetics: Messrs. T. Gunton Alderton and Rickard W. Lloyd. Assistant Administrator of Anæsthetics: Mr. E. W. Lewis. Electrician: Dr. W. A. Turner. Secretary: Mr. R. J. Gilbert. The practice of the Hospital is open to Post-graduates (on payment of a small fee); no junior students are admitted, but clinical assistants are appointed to the wards, and out-patient department. Courses of post-graduate lectures are given by the staff on Wednesdays at intervals, particulars of which are advertised in the medical journals. The hospital is recognised by the Conjoint Board of the Royal Colleges of Physicians and Surgeons as an institution where 6 months of the fifth year of study may be passed. The course of ophthalmology is recognised by the Army Medical Department. Further information can be obtained on application to the Dean, Mr. L. A. Bidwell, at the hospital.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E. For the sick children of the poor under twelve years of age. Established 1867. City Offices: 27, Clement's-lane, E.C.—Fifty-seven beds. Last year 705 in-patients and 15,272 out-patients (representing 55,149 attendances) were relieved, 180 of the in-patients being under two years of age. Consulting Physicians: Drs. A. E. Sansom, W. Cayley, and F. C. Turner. Consulting Surgeons: Messrs. Jonathan Hutchinson, Waren Tay, R. J. Godlee and Bilton Pollard. Physicians: Drs. W. A. Wills, James Taylor, J. H. Sequeira, and J. Porter Parkinson. Surgeons: Messrs. H. Percy Dean and (vacancy). Three Resident Medical Officers. Ophthalmic Surgeon: Mr. Sydney Stephenson (Wednesday, 9.30 A.M.). Dental Surgeon: Mr. John W. Pare (Tuesday and Friday, 9.30 A.M.). Matron: Miss E. W. Curno. Secretary: T. Glenton-Kerr. The surgeons attend on Wednesdays at 2 P.M. and Fridays at 9 A.M.; the physicians daily at 2 P.M. Applications for permission to attend the practice of the hospital should be addressed to the secretary.

NORTH-WEST LONDON HOSPITAL, Kentish Town-road.—Consulting Physician: Dr. Donald W. C. Hood. Physician: Dr. Harry Campbell. Surgeon: Mr. Frederic Durham. Assistant Physicians: Drs. W. Knowsley Sibley, Leonard G. Guthrie, and James Cagney. Assistant Surgeons: Messrs. M. P. Mayo Collier, J. Jackson Clarke, and George Templeton. Physician for Diseases of the Skin: Dr. J. Herbert Stowers. Obstetric Physician: Dr. John Shaw. Ophthalmic Surgeon: Dr. W. J. Collins. Dental Surgeon: Mr. C. F. Rilot. The hospital, which was established in 1878, provides 53 beds. The average number occupied last year was 47. It is a general hospital. There are two spacious wards for men and women respectively. The children's wards contain 18 cots. There are two Resident Medical Officers—an honorarium at the rate of £50 per annum attaches to the senior post. Operation day, Thursday at 2.30 o'clock. Further particulars from J. Herbert Stowers, M.D., Hon. Sec., Medical Committee, 128, Harley-street.

ROYAL EYE HOSPITAL, St. George's-circus, Southwark, S.E.—There are 40 beds and 2 cots. There were upwards of 46,000 attendances in the Out-patient Department last year, and the new patients number over 16,000 yearly. Operations are performed and out-patients are seen daily at 2 P.M. The following are the days of attendance:—Mr. M. M. McHardy, Tuesdays; Mr. J. G. Mackinlay, Thursdays; Dr. W. J. Collins, Wednesdays and Fridays; and Mr. L. V. Cargill, Mondays and Saturdays. Qualified practitioners and students are admitted to the practice of the hospital upon the recommendation of the medical staff. Fees: £2 2s. for 3 months, £3 3s. for 6 months, and £5 5s. perpetual. Qualified students of the hospital are eligible for the offices of registrar and house surgeon, and may be appointed clinical assistants upon the recommendation of the medical staff for a term of 6 months, and are eligible for re-election. Courses are held on Ophthalmoscopy, Refraction and Diseases of the Eye, fee, £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology Class, £1 1s. extra to cover cost of materials. Tutorial or coaching classes for the various examinations arranged as far as possible to suit candidates.

COOKE'S SCHOOL OF ANATOMY.—The school is prepared to admit to its supplementary work all who may wish to join the same, but in regard to its curriculum work it does not receive more than half-a-dozen students in the course of the year. These curriculum students are carefully selected as to ability and are offered thorough practical instruction. The charges are but slightly in excess of current charges. The Bland Sutton Presentation, named after Mr. Bland Sutton, F.R.C.S., Sir Erasmus Wilson Lecturer at the Royal College of Surgeons, Surgeon to the Middlesex Hospital, &c. (a former pupil of the school), confers the privilege of free medical education during the first two years of medical studies. Particulars will be forwarded on application. The school remains open for anatomical work, not only

Digitized by Google

during the winter, but also during the summer months. Gentlemen rejected at their Anatomical and Physiological Examinations (Second Conjoint, &c.) can get 'signed up" from this school for the three or six months' supplementary work they are now required to put in before re-examination. This school is also intended to meet the requirements of qualified practitioners wishing to obtain some of the higher qualifications, and is recognised for the special dissections for the Fellowship of the Royal College of Surgeons. The school possesses a good collection of physiological apparatus. The operations of Surgery are performed by the students on the dead body. Private address: 40, Brunswick-square, W.C.

VOLUNTEER MEDICAL STAFF CORPS (LONDON COMPANIES), Calthorpe-street, Gray's-inn-road, W.C. — Hon. Commandant: Surgeon-General Sir William Guyer Hunter, K.C.M.G., Q.H.S., V.D. Commandant: Surgeon-Lieutenant-Colonel A. T. Norton. The Volunteer Medical Staff Corps bears the same relation to the Volunteer Army as the Medical Staff Corps bears to the regular Army. The course of training has the great advantage of affording, in addition to a knowledge of ordinary military duties, special ambulance instruction useful in all ranks of life. All who have gone through the ranks of this corps are capable of rendering valuable aid in any accident, and in cases of emergency may be the means of saving lives which would otherwise be lost. In addition to the Company and Battalion drills of an ordinary infantry corps, the special training includes stretcher and waggon, and cacolet drill; the use of improvised seats and stretchers; the use and application of bandages, splints &c.; lectures by the officers on first aid to the injured, and on the elements of anatomy, physiology, hygiene, and nursing, which are so arranged as not to interfere with the lectures &c. carried on at the various hospitals in London. There is also a Shooting Club in the corps, in which instruction in, and facilities for, the practice of rifle shooting are given. There is a Transport Section in connexion with the corps, the members of which go through a course of instruction in riding and driving and transport work with the regular troops. There are also sections of Cyclists and Signallers. A Gymnastic Class meets once a week at headquarters, under an instructor who teaches boxing and fencing; "the class is under the special direction of the adjutant and officers, who see that the exercises are consistent with the physical development of the men, an advantage possessed by no other Volunteer corps." Lectures are delivered during the winter session. The new headquarters contain a fine drill hall, mess-rooms, canteen, &c., where dinners, suppers, dances, and smoking concerts can be held at any time. The Adjutant, Surgeon-Captain G. T. Rawnsley, will give any information respecting the above on application to the headquarters, Calthorpe-street, Gray's-inn-road, W.C.

SCHOOL OF THE PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—Chemistry and Physics: J. Norman Collie, Ph.D., F.R.S. Botany: Professor Reynolds Green, M.A., Sc.D., F.R.S., F.L.S. Materia Medica: Professor Greenish, F.I.C., F.L.S., Dean of the school. The session commences on Monday, Oct. 4th. Medical students, or pupils intending to enter the medical profession, are admitted to the lectures and laboratory work in any or all the courses. Certificates of instruction in this school are received by the Conjoint Board of the Royal Colleges. Application for admission to the school, or for further information, may be made to the Secretary of the school, 17, Bloomsbury-square, London, W.C.

THE CITY SCHOOL OF CHEMISTRY AND PHARMACY, LIMITED, 27, Chancery-lane, W.C.—This school was established in 1882 for the advancement of pharmaceutical education. Lecturers and Demonstrators—Chemistry, Physics, and Pharmacy: Mr. F. A. Hocking, B.Sc. Lond., M.P.S., Ph.C; Materia Medica, Botany, and Prescription Reading: Mr. W. Roberts, M.P.S.; Microscopy and Vegetable Histology: Mr. Martin J. Cole (Microscopist to the Birkbeck Institute); Analytical Chemistry and Practical Pharmacy: Mr. F. A. Hocking, B.Sc., Mr. W. Roberts, M.P.S.; Biology (Practical and Theoretical): Mr. L. Orchard, M.A. (Professor of Biology, Univ. College, Lond.). Application for particulars should be made to the Principal, Mr. G. E Skerry, M.A. Classes recognised by General Medical Council and Apothecaries' Hall.

WESTMINSTER COLLEGE OF CHEMISTRY AND PHARMACY, Trinity-square, Borough, S.E.—Established 1872. Principals, G. S. V. Wills, F.L.S., M.P.S., and H. Wootton, B.Sc. Lond. Instruction is given in Chemistry and Physics, Materia Medica, and Pharmacy (Practical and Theoretical), suitable for Medical and Dental students. Nurses and others can also be prepared for the Apothecaries' Hall Dispenser's certificate. Evening classes for Dispensing. Full particulars from E. Walden, Secretary.

GRIFFITHS'S COLLEGE OF CHEMISTRY AND PHARMACY, 12, Knowle-road, Brixton, S.W.—Instruction is given in Chemistry, Physics, Botany, Biology, Pharmacy, Materia Medica, Microscopy, Toxicology, &c., for the examinations of the Apothecaries' Hall, Conjoint Board, First M.B. London, Durham, special examinations for B.A. of Cambridge. During the past academic year 36 candidates passed the examinations of the Pharmaceutical Society, 9 passed the Hall, 7 passed the London Preliminary Science, 1 passed Durham, 2 passed the First M.B. London. This college (which supplements the work of the medical schools) has excellent laboratories, microscopical and Materia Medica specimens, and is fitted with every convenience and apparatus for practical work. Backward students may rely upon the most thorough attention being paid to them in every way. The college is reached in 15 minutes (by tram) from Westminster. Particulars as to fees may be had from Dr. A. B. Griffiths, F.R.S. Edin., F.C.S., at the above address.

ROYAL COLLEGE OF SCIENCE, London (with which is incorporated the ROYAL SCHOOL OF MINES).—Mechanics and Mathematics: Professor J. Perry, F.R.S. Biology: Professor G. B. Howes, F.R.S. (Zoology), and Professor J. B. Farmer, M.A. (Botany). Chemistry: Professor W. A. Tilden, F.R.S., and Dr. W. P. Wynne, F.R.S. Physics: Professor A. W. Rücker, Sec. R.S., and Mr. W. Watson, B.Sc. Astronomical Physics: Professor J. N. Lockyer, C.B., F.R.S. Geology: Professor J. W. Judd, C.B., F.R.S. Metallurgy: Professor W. C. Roberts-Austen, C.B., F.R.S. Mining: Professor C. Le Neve Foster, F.R.S. Agriculture: Professor J. Wrightson. The College re-opens on Wednesday, Oct. 6th, 1897. Communications should be addressed to the Registrar, Royal College of Science, South Kensington, S.W.

ELECTRICAL STANDARDIZING, TESTING, AND TRAINING INSTITUTION, Faraday House, 8 and 10, Charing-cross-road, W.C.—Principal, Mr. Hugh Erat Harrison, B.Sc. Lond., F.C.S., A.M.I.C.E., M.I.E.E. Instructor in Mathematics: Alexander Russell, M.A. Glasgow and Cambridge. Instructor in Chemistry: Chas. J. Wilson, F.I.C., F.C.S. This institution, in addition to its ordinary course of training in electrical engineering, which occupies two or three years, also arranges for special instruction in all branches of electricity and in Roentgen Ray photography, either by private tuition or by a specially arranged course at the college or at the works of the companies with which it is associated. There are Entrance Scholarships of the value of 80 and 50 guineas, and Exhibitions of 40 guineas. Particulars may be obtained on application to the Secretary, Mr. Howard Foulds, Faraday House, Charing-cross-road, W.C.

PROVINCIAL MEDICAL SCHOOLS AND HOSPITALS HAVING SPECIAL CLASSES AND FACILITIES FOR CLINICAL STUDY.[1]

MASON COLLEGE, BIRMINGHAM.—Two Ingleby Scholarships are offered annually after examination in Obstetric Medicine and Surgery and Diseases of Women and Children. The Scholarships are open to students who have completed two years of their curriculum in this college. One or more Sydenham Scholarships are offered annually of the value of 30 guineas each. The orphan sons of former students of the Birmingham Medical School have priority of election. No Sydenham scholars are elected whose age exceeds twenty-three years on the day of election. The Scholarships are held for three years, subject to good behaviour. A Queen's Scholarship is offered annually of the value of 30 guineas. It may be held for three years, one-third being paid each year, subject to good behaviour. A Sands Cox Scholarship is offered annually, of the same value as the last, and is held under similar conditions. The Russell Memorial Prize is awarded annually after examination in Nervous Diseases. There are Faculties of Arts,

[1] For Scholarships see page 493 *et seq.*

Science, and Medicine, and students are prepared for the various examinations of the University of London. The medical courses qualify for the diplomas of all Licensing Bodies and for the degrees in Medicine and Surgery of British Universities. There are various Scholarships, Entrance and otherwise. The Dental Department, in conjunction with the General, Queen's, and Dental Hospitals, affords a complete curriculum for all Dental diplomas. The Library contains upwards of 24,000 volumes. Syllabuses containing full information as to the various courses of instruction, lecture days and hours, fees, scholarships, &c., will be forwarded on application to the Registrar.

THE QUEEN'S HOSPITAL, BIRMINGHAM. — Consulting Physician: Sir James Sawyer, Knt., M.D., F.R.C.P., F.R.S.E., J.P. Consulting Surgeons: Furneaux Jordan, F.R.C.S., and J. St. S. Wilders, M.R.C.S. Physicians: Alfred H. Carter, M.D., F.R.C.P., Cornelius W. Suckling, M.D., M.R.C.P., and Arthur Foxwell, M.A., M.D., F.R.C.P. Surgeons: Bennett May, B.S., F.R.C.S., Jordan Lloyd, M.S., F.R.C.S., and Frank Marsh, F.R.C.S. Ophthalmic Surgeon: Priestley Smith, M.R.C.S. Obstetric Officer: C. E. Porslow, M.D., M.R.C.P. Physicians for Out-Patients and Pathologists: O. J. Kauffmann, M.D., M.R.C.P., and J. Douglas Stanley, M.D., M.R.C.P. Casualty Surgeons: J. T. J. Morrison, M.A., B.C., F.R.C.S., J. Hazlewood Clayton, M.B., M.R.C.S., and C. A. Leedham Green, F.R.C.S. Provision has recently been made for an increase in the number of beds to 132 for the reception of accidents and urgent medical, surgical, ophthalmic, and obstetric cases. The in-patients treated last year amounted to 2109, the out-patients to 28,820.

GENERAL HOSPITAL, BIRMINGHAM.—Consulting Physicians: Dr. Fletcher, Sir Walter Foster, and Sir Willoughby Wade. Physicians: Drs. Rickards, Saundby, Simon, and Wilson. Surgeons: Messrs. Chavasse, Barling, Haslam, and Heaton. Obstetric Officer: Dr. Malins. Assistant Physicians: Drs. Short and Russell. Assistant Surgeons: Messrs. Lucas and Gamgee. Assistant Obstetric Officer: Dr. Thos. Wilson. Beds, 271; average occupied, 238. Patients in 1896: in-patients, 4486; out-patients, 52,203.

UNIVERSITY COLLEGE, BRISTOL (Faculty of Medicine).—Students can complete in Bristol the entire course of study required for the Medical and Surgical degrees of the University of London, and for the diplomas of the Royal College of Physicians of London and the Royal College of Surgeons of England, the Apothecaries' Society of London, and the Army and Navy Boards. The lectures and instructions given in the Faculty of Arts and Science are adapted to the various Preliminary Arts Examinations above referred to, and also to the Matriculation and Preliminary Scientific Examinations of the University of London; whilst the Faculty of Medicine, the Royal Infirmary, and the General Hospital together provide for every detail of the professional curriculum required by the University of London and the above examining boards. All necessary information may be obtained from the Dean of the Faculty of Medicine, Professor E. Markham Skerritt, M.D., F.R.C.P.

UNIVERSITY COLLEGE, CARDIFF, MEDICAL SCHOOL.—Owing to the very rapid increase in the population of Glamorganshire and Monmouthshire, and the consequent increase in the Infirmary accommodation, the basis on which to build a Medical School in South Wales is amply sufficient for every need. University College, Cardiff, has for some years past prepared students in Physics, Chemistry, Zoology, and Botany; and these students have in considerable numbers passed these subjects as part of their medical curriculum and have finished their studies elsewhere. The recent appointments of a Professor of Anatomy, a Professor of Physiology, and of a Lecturer on Materia Medica and Pharmacy will afford facilities to students who may wish to continue their studies in Cardiff until the end of their third year. Large laboratories are now ready; they comprise spacious lecture-rooms to seat 100 students each, a dissecting-room, anatomical museum, bone-room, and preparation-room; a class-room for practical physiology, physiological preparation and research rooms, and photographic and instrument-rooms, and museum of Materia Medica. Students preparing for the Preliminary Scientific and Intermediate Examination in Medicine of the University of London or Durham may compound for their classes by paying a composition fee of £57 10s. The College classes are recognised by the Scottish Universities. Students who are preparing for the examinations of the Conjoint Board or of the Society of Apothecaries, London, may compound for their classes by paying a composition fee of £35. In all cases the composition fees may be paid in instalments. Twenty-two Exhibitions and Scholarships, open to intending students of medicine, will be competed for in September next. For particulars of these application may be made to the College Registrar. Physics.—Professor J. Viriamu Jones, M.A. Oxon., B.Sc. Lond., Fellow of University College, London, F.R.S. Assistant Professor: A. L. Selby, M.A., Fellow of Merton College, Oxford. Demonstrator and Assistant Lecturer: W. S. Hensley, B.A., Christ's College, Cambridge. Chemistry. — Professor C. M. Thompson, M.A., Trinity College, Cambridge, D.Sc. Lond., F.C.S. Assistant Lecturers: E. P. Perman, D.Sc. Lond., and A. A. Read, F.I.C., F.C.S. Biology. — Professor W. N. Parker, Ph.D. Freiburg, F.Z.S. Assistant Lecturer: A. H. Trow, B.Sc. Anatomy.— Professor Francis Dixon, B.A., M.B. Physiology.—Professor John Berry Haycraft, M.D., D.Sc., F.R.S.E. Materia Medica: D. R. Paterson, M.D. The Infirmary, within three minutes of the College, is provided with 200 beds. Attached to the hospital is a large out-patient department and special departments for the Eye, Ear, and Throat. Further information may be obtained from Dr. John Berry Haycraft, Dean of the Medical Faculty.

BRISTOL ROYAL INFIRMARY (Founded 1735).—270 beds. Honorary and Consulting Physicians: Dr. Edward Long Fox and Dr. William H. Spencer. Honorary and Consulting Surgeons: Mr. Augustin Prichard and Mr. Edmund C. Board. Physicians: Dr. R. Shingleton Smith, Dr. Henry Waldo, Dr. John E. Shaw, and Dr. Arthur B. Prowse. Obstetric Physician: Dr. W. C. Swayne. Assistant Physicians: Dr. P. Watson Williams and Dr. F. H. Edgeworth. Surgeons: Mr. Arthur W. Prichard, Mr. W. H. Harsant, and Mr. J. Paul Bush. Ophthalmic Surgeon: Mr. F. Richardson Cross. Assistant Surgeons: Mr. G. Munro Smith and Dr. James Swain. Dental Surgeon: Mr. W. R. Ackland. Pathologist: Dr. Theodore Fisher. House Surgeon: Dr. Thomas Carwardine. House Physician: Mr. H. F. Mole. Resident Obstetric Officer: Mr. J. C. McWatters. Anæsthetist: Mr. W. H. Cooper. Casualty Officer: Mr. T. W. Bovey. Secretary and House Governor: Mr. E. A. Leonard.

Scholarships and Prizes.—Two Entrance Scholarships, 35 guineas and 10 guineas: examination third Saturday in October in general subjects; Surgical and Medical Suple Gold Medals, 5 guineas each, with 7 guineas added in money; Clark Prize, 11 guineas; Crosby Leonard Prize, 7 guineas; Tibbitts Prize, 9 guineas; Midwifery Prize, 3 guineas in books or instruments; Pathological Prize, 6 guineas; Ophthalmic Prize, 3 guineas in books or instruments; Dental Prize, 3 guineas in books or instruments.

There are five resident appointments—viz., House Surgeon, House Physician, Resident Obstetric Officer, Anæsthetist, and Casualty Officer, the last two of which are intended specially for qualified students of the Bristol Royal Infirmary, who are elected after a practical examination. Medical Registrars and Surgical Registrars are appointed for periods of six months. The Dressers reside in the Infirmary in rotation, free of expense. The Maternity student also has rooms in the Infirmary. The whole of the clinical work is carefully arranged to meet the requirements of the five years' curriculum. There is class instruction in the wards by the physicians and surgeons on five days a week, in addition to the regular clinical lectures. There are special departments for Diseases of Women, the Eye, Ear, Throat, &c., with Clerkships and Dresserships attached, and there is a large Ward for Children only. Practical instruction in Dental Surgery on Tuesdays and Fridays. Clinical Clerkships and Dresserships, 5 guineas for each six months. Perpetual Medical and Surgical Practice, 35 guineas in one sum.

Further information can be obtained from Dr. Arthur B. Prowse, Dean of the Faculty.

BRISTOL GENERAL HOSPITAL.—200 beds. Physicians: Drs. Markham Skerritt, Harrison, and Michell Clarke. Physician Accoucheur: Dr. W. H. C. Newnham. Physician to Throat and Nose: Dr. Barclay Baron. Assistant Physician: Dr. Parker. Assistant Physician Accoucheur: Mr. F. C. Rayner. Surgeons: Messrs. Pickering, Barclay, Morton, and Lansdown. Ophthalmic Surgeon: Mr. Walker.

Digitized by Google

Assistant Surgeon: Dr. Firth. Anæsthetist: Mr. Freeman. House Surgeon: Dr. Randall. Physicians' Assistant: Mr. Druitt. Assistant House Surgeon: Mr. Hewetson. Casualty Medical Officer: Mr. Edwards. Clinical Clerkship, six months, £5 5s. Dressership, six months, £5 5s. Obstetric Clerkship, three months, £3 3s. Special clinical instruction is given in Diseases of the Skin, Eye, Ear, and Throat, also in Diseases of Women and in Dental Surgery. Further information may be obtained of the Secretary, at the hospital, or from Dr. Michell Clarke, Dean of the Hospital Faculty.

Scholarships and Medals. — Lady Haberfield Entrance Scholarship: This Scholarship, founded in 1875, of the value of about £30, being the interest of £1000 bequeathed for the purpose by the late Lady Haberfield, is awarded annually at the commencement of the winter session after a competitive examination in subjects of general education. Second Entrance Scholarship: An additional Entrance Scholarship of the value of £20 is awarded when more than six candidates present themselves. Clarke Scholarship: A Surgical Scholarship, of the value of £15, founded by H. M. Clarke, Esq, of London, is awarded annually at the end of the winter session after an examination in Surgery. Sanders Scholarship: A Scholarship founded by the late John Nash Sanders, Esq., of the value of £22 10s., is awarded annually at the end of the winter session after examination in Medicine, Surgery, and Diseases of Women. Martyn Memorial Pathological Scholarships, founded in 1878 by public subscription, in memory of the late Dr. Samuel Martyn, Physician to the hospital: Two Scholarships, each of the value of £10, are awarded annually: one at the end of the summer session and one at the end of the winter session. A student may, at the option of the Faculty, hold both these Scholarships. After a competitive examination in Pathology and Morbid Anatomy the successful candidate is appointed Pathological Clerk to the hospital for the term of six months. Committee Gold Medal: This medal, presented by the committee of the hospital, is awarded annually at the end of the winter session to the student of the fifth year who has most distinguished himself during his career at the hospital and medical school. Committee Silver Medal: This medal, presented by the committee of the hospital, is awarded annually at the end of the winter session to the next most distinguished student of the fifth year. The rules relating to the several Scholarships may be had on application.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—Clinical Lectures in Medicine and Surgery, in connexion with Cambridge University Medical School, are delivered at this hospital twice a week during the academical year; and practical instruction in Medicine and Surgery in the wards and out-patients' rooms is given by the physicians and surgeons daily, during the vacations as well as term time. Instruction is also given in all the special modes of medical and surgical investigation. Clinical Clerks and Dressers are selected from students according to merit, and without payment. The composition fee for pupilship is 8 guineas.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE, Newcastle-upon-Tyne.—The following Scholarships and Prizes are awarded annually:— Four University of Durham Scholarships, value £25, tenable for four years, for proficiency in Arts, awarded to full students in their first year. The Dickinson Scholarship, value interest of £400, and a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value the interest of £400, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value the interest of £700, for Medicine. The Gibb Scholarship, value the interest of £500, for Pathology. The Goyder Memorial Scholarship (at the Infirmary), value the interest of £325, for Clinical Medicine and Clinical Surgery. The Luke Armstrong Memorial Scholarship, value the interest of £680 for Comparative Pathology. The Stephen Scott Scholarship in Surgery, value the interest of £1000. Heath Scholarship: The late George Yeoman Heath, M.D., D.C.L., F.R.C.S., President of the University of Durham College of Medicine, bequeathed the sum of £4000 to found a Scholarship in Surgery, the interest to be awarded every second year; the next award will be in 1898. The Gibson Prize, interest on £225, in the department of Midwifery and Diseases of Women and Children. At the end of each session Prizes of Books and Honours Certificates are awarded in each of the regular classes. Assistant Demonstrators of Anatomy, receiving each an honorarium of £5, Prosectors, and Assistant Demonstrators of Physiology and Pathology are elected yearly. Pathological Assistants, Assistants to the Dental Surgeon, Assistants in the Eye Department, Throat and Ear Department, and Skin Department, Clinical Clerks, and Dressers are appointed every three months.

NEWCASTLE-UPON-TYNE ROYAL INFIRMARY. — Physicians: Drs. Drummond, Oliver, Limont, and Murray. Surgeons: Drs. Hume, Page, Mr. Williamson, and Mr. Rutherford Morison. Assistant Surgeons: Mr. Walter Ridley, Mr. A. M. Martin, Mr. H. B. Argus, and Mr. I. V. W. Rutherford. Pathologist: Dr. Beattie. Dental Surgeon: Mr. R. L. Markham. Skin Department: Dr. Limont. Eye Department: Mr. Williamson. Throat and Ear Department: Mr. Ridley. Anæsthetist: Dr. W. D. Arnison. Surgical Registrars: Mr. T. D. Wardale and Mr. John Clay. The infirmary contains 280 beds. Clinical Lectures are delivered by the Physicians and Surgeons in rotation. Pathological Demonstrations are given by the Pathologist as opportunity offers. Practical Midwifery can be studied at the Newcastle Lying-in Hospital. Instruction is given in Psychological Medicine at the Northumberland County Asylum, Morpeth. A Special Course of Instruction is given in the City Hospital for Infectious Diseases by the Superintendent, the City Officer of Health, Mr. H. E. Armstrong.

LEEDS GENERAL INFIRMARY AND MEDICAL DEPARTMENT OF THE YORKSHIRE COLLEGE.—The Leeds General Infirmary has accommodation for 447 in-patients, medical and surgical, including forty-two beds at a "semi-convalescent home" in the country. During the last year 6116 in-patients and 37,623 out-patients were treated. Clinical teaching takes place daily in the wards, and Clinical Lectures are given in Medicine and Surgery by the Physicians and Surgeons. There are Medical, Surgical, Ophthalmic, Aural, and Electrical Departments, in each of which special instruction is imparted to students. A Gynæcological and Extern Obstetric Department, together with Laryngeal and Skin Clinics, are in operation. The Public Dispensary, the Hospital for Women and Children, the Fever Hospital, and the West Riding Lunatic Asylum are other medical institutions which are made use of by the Leeds students. Three years ago the new buildings of the Medical School were opened by their Royal Highnesses the Duke and Duchess of York. Erected on a commanding site, close to the Infirmary, the new School of Medicine contains complete accommodation for the training of medical students upon the most approved modern methods. A very fine dissecting-room, extensive laboratories for Physiology and Pathology, with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large Library, and separate Museums for Pathology and Anatomy—these are some of the most striking features of the new buildings. Careful provision for the convenience of students, in the shape of a common-room, a refectory, &c., has also been made a feature of the school. The classes in Systematic and Practical Chemistry, Physics and Biology, and Practical Toxicology are held in the Science and Arts Department of the College, in College-road. Two Entrance Scholarships are offered: one, of the value of 64 guineas, covering admission to all requisite lectures; and the other, of the value of 40 guineas, covering the cost of admission to the medical and surgical practice of the infirmary. Several valuable prizes are given at the end of each session. The following appointments at the infirmary are annually open to students (for some of them, however, a registered legal qualification is required); senior and junior anæsthetists, pathological curator, resident medical officer, resident surgical officer, resident casualty officer, resident ophthalmic officer, appointed for twelve months, and eligible for re-election; resident obstetric officer and 4 house surgeons, for twelve months; 2 house-physicians, for six months; 36 physicians' clerks, for six months; 32 surgeons' dressers, for six months; 16 ophthalmic and aural surgeons' dressers, for three months; 16 gynæcological ward clerks, for three months; 12 gynæcological out patient clerks, for three months; 32 assistant physicians' clerks, for three months; 32 assistant surgeons' dressers, for three months; 32 dressers in the casualty-room, for three months; 32 post-mortem clerks, for three months.

There are appointments open to students in other medical

institutions in the town and also in the West Riding Lunatic Asylum.

UNIVERSITY COLLEGE, LIVERPOOL: MEDICAL FACULTY.—The new Physiological and Pathological Laboratories are now in course of erection, and will be ready for occupation during the Winter Session (1897-98). The Chemical Laboratories have been extended at a cost of about £10,000, so as to provide *inter alia* more complete accommodation for medical students and those engaged in Laboratory work for Diplomas in Public Health. Steps are being taken for the extension of the Anatomical Department, and the first instalment of new Anatomical and Surgical Laboratories has been already erected at a cost of £2000 in the form of permanent Anatomical out-buildings and court-yard. The buildings include mortuary, store-rooms, museum work-rooms, and macerating room, along with lavatories, &c. The erection of new Anatomical and Surgical Laboratories will be commenced as soon as practicable. The dissecting-room and theatre have been provided with the electric light. The chair of Pathology has adequate temporary accommodation in Ashton Hall, an institute adjacent to the College, which contains ample class-room and laboratory accommodation for study and research in Pathology and Bacteriology. The museums of Anatomy, Pathology, Materia Medica, and Public Health are furnished with complete provision for the needs of students and have recently been re-organised and revised.

Fees. — The composition fee for lectures and classes is £24 15*s.* for Preliminary Science Classes; £60 for the Medical Classes required for the Victoria University degrees; £70 for all the classes required for the diplomas of the Conjoint Boards. The medical composition fees are payable in two instalments at intervals of twelve months. The fee for hospital attendance at the Royal Infirmary is 40 guineas, also payable in two annual instalments.

Appointments.—Three house surgeons, three house physicians, and one external house surgeon to the Thornton Wards are appointed for six months after (if necessary) competitive examination. Candidates must have a legal qualification. Three clinical clerks for each physician, three or more dressers for each surgeon, and two clerks to the Thornton Wards for Diseases of Women are appointed every three months. Post-mortem clerks are appointed for six weeks; all students are required to perform this duty before the schedule for the Final Examination is signed. Clinical assistants are appointed from among the senior students.

There is a School of Dental Surgery in connexion with the medical faculty. The curriculum includes Lectures and Demonstrations on all the subjects required for the Licences in Dental Surgery of the Royal Colleges of Surgeons of London, Edinburgh, and Dublin, and of the Faculty of Physicians and Surgeons of Glasgow. In addition, Laboratory Courses are conducted in Dental Histology and Dental Pathology.

Practical instruction in Dentistry is given at the Dental Hospital in Mount Pleasant.

Fees.—A payment of £50 on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months), entitles the student to attendance on all lectures and demonstrations (medical and special) required for the Dental Licence of the Royal College of Surgeons. The fee for two winters' surgical practice is £10 10*s.*, and for two years' dental hospital practice, £12 12*s.* The total expenditure for the whole curriculum is £73 2*s.*

Further information can be obtained from the Dean of the Medical Faculty, Professor Paterson, University College, Liverpool.

SCHOOL OF PHARMACY.—A department of Pharmacy has recently been instituted, comprising the necessary courses for the minor and major examinations of the Pharmaceutical Society in Chemistry, Physics, Botany, Materia Medica and Pharmacy. The composition fee is £17, and the classes may be attended in one or two years.

Prospectus and further information may be had on application to the Registrar, University College, Liverpool.

MEDICAL DEPARTMENT OF OWENS COLLEGE, VICTORIA UNIVERSITY.—This medical school is located in a large building, which forms a part of Owens College. It is provided with large dissecting-rooms, physiological laboratories, private laboratories, and work-rooms, besides lecture-rooms, a museum, and a library. In order to give the fullest possible opportunities for teaching and investigation in the departments of Anatomy, Physiology, Pathology, and Materia Medica, an extension of the school buildings has recently been made. The greater part of the new buildings is devoted to the departments of physiology, pathology, toxicology, anatomy, and public health. The physiological department occupies more than half of the new buildings, and includes a large lecture theatre, accommodating 350 students, with preparation and diagram rooms adjacent to it, and a research laboratory fitted with the necessary apparatus for the use of advanced students, research scholars, or practitioners of medicine undertaking the investigation of some special subject. In the new pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research. In the toxicological department there is a large laboratory, capable of accommodating fifty students, lighted from both sides and also from the roof, completely equipped with all that is necessary for the practical teaching of toxicology; also a small laboratory for private research, containing the apparatus and fittings necessary for investigations in toxicological chemistry. In the public health department suitable laboratory accommodation is provided for the study of sanitary chemistry, physics, and practical bacteriology in the departments of chemistry and physics and in that of pathology. A large room is provided in the new buildings for a museum of apparatus, models, plans, and other sanitary appliances for the practical instruction of the students, together with a special library of works on State medicine, hygiene, vital statistics, and sanitary engineering. In addition, a large lecture theatre for general purposes, accommodating 250 students, has been provided, and the existing accommodation for students is supplemented by the provision of a larger common room. The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary, as well as in a fever hospital, a lunatic asylum, and a convalescent home. Medical and Surgical Clinical Classes are conducted in the infirmary, and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine, Ophthalmic Surgery, and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary. The following entrance scholarships are offered for award to persons proposing to enter a medical course of study at the College:—Seaton.—One of £40, tenable for two years. Subjects: Greek and Latin Translation at sight, and Prose Composition. Credit given for knowledge of Mathematics (Geometry and Algebra); Elements of English Language, Literature, and History; French and German. Rogers.—One of £40, tenable for two years. Subjects as in Seaton. Dalton.—Two of £40, tenable for two years. Subjects: Geometry (Euclid I.—IV., and VI., or the subjects thereof); Algebra (as far as the Binomial Theorem, inclusive); Plane Trigonometry (to Solution of Triangles); Elementary Analytical Geometry; Conic Sections. Credit given for knowledge of Classics, Elements of English Language, Literature, and History; French and German. Cartwright.—£35 per annum, tenable for three years. Subjects as in Dalton. Hulme.—£35, tenable for three years. Subjects: English Language (Grammatical Structure and Outlines of its History); English Literature (an essay on some subject of English literature); and Modern History (Outlines of English History and Geography); with at least two of the following: Latin (Translation at sight, Grammar, and Easy Composition); Greek (ditto); French (ditto); German (ditto). Credit given for knowledge of Mathematics (Geometry and Algebra). James Gaskill.—£40, tenable for two years. Subjects: Mathematics, Geometry (the substance of Euclid I.—IV. and VI.), Algebra (as far as the Binomial Theorem, inclusive), Plane Trigonometry (to Solution of Triangles), Elementary Mechanics, Chemistry. Credit given for knowledge of Classics, Elements of English Language, Literature, and History, and French and German. Manchester Grammar School.—£18 per annum, tenable for three years. The examinations for all these scholarships are held in the month of May. Kay-Shuttleworth (Sir James Phillips). — £30 per annum, tenable for three years. Subjects: Mathematics, Elementary Mechanics, Chemistry. Dauntesey Medical Scholarships.—Two Scholarships of £35 each are open to all students preparing for a medical course who shall not have attended lectures or Laboratory courses on human anatomy or physiology, or a purely medical or surgical course in the Owens College or any other Medical

Digitized by Google

School in the United Kingdom. Candidates will be examined in Zoology, Botany, and Chemistry. Medals are awarded on the results of the various class examinations at the end of each session. A Platt Physiological Scholarship of £50 a year for two years is offered annually to the student who, having studied for one entire session in the Physiological Laboratory of Owens College, has prosecuted the best original investigation in Physiology and has passed a satisfactory examination in Physiology. Two Platt Exhibitions, of the value of £15 each, to be competed for by first and second year students in the class of Physiology. A Dumville Surgical Prize of £15 is offered annually for proficiency in Clinical Surgery. The Turner Medical Scholarship of £20 is awarded annually. The John Henry Agnew Scholarship in Diseases of Children (£30) is also offered for competition each year. Medical and Surgical Clinical Prizes, each of the value of 6 guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary.

MANCHESTER ROYAL INFIRMARY (300 beds).—Consulting Physicians: Drs. Frank Renaud, H. Browne, Sir Wm. Roberts, and Henry Simpson. Consulting Surgeons: Messrs. George Bowring, E. Lund, and F. A. Heath. Physicians: Drs. D. J. Leech, J. Dreschfeld, Graham Steell, and Thos. Harris. Assistant Physicians: Drs. J. S. Bury and A. T. Wilkinson. Consulting Obstetric Physician: Dr. Lloyd Roberts. Obstetric Physician: Dr. Archibald Donald. Surgeons: Messrs. Walter Whitehead, Thomas Jones, Jas. Hardie, and F. A. Southam. Assistant Surgeons: Messrs. G. A. Wright and Wm. Thorburn. Ophthalmic Surgeon: Dr. D. Little. Dental Surgeon: Mr. G. W. Smith. Pathological Registrar: Dr. T. N. Kelynack. Medical Registrar: Dr. R. T. Williamson. Surgical Registrar: Mr. H. W. Pomfret. Administrators of Anæsthetics: Mr. Alexander Wilson and Mr. J. W. Smith. Assistant Medical Officers for Home Patients: Mr. W. B. Pritchard and Mr. G. E. Fryer. General Superintendent and Secretary: Mr. W. L. Saunder.

BARNES CONVALESCENT HOSPITAL, Cheadle, Cheshire (in connexion with the Manchester Royal Infirmary; 136 beds).—Secretary: Mr. W. L. Saunder. Resident Medical Officer: Mr. A. R. Stillwell Freeland.

RADCLIFFE INFIRMARY, Oxford (120 beds).—At this infirmary instruction is given to medical students attending Oxford University. Clinical lectures are given by the Lichfield Clinical Lecturers in Medicine and Surgery. Also tutorial instruction and demonstrations are given in special Regional Anatomy (medical and surgical), methods of Medical Diagnosis, and Surgical Manipulation. Demonstrations of Elementary Pathology are given in the post-mortem room and at the Pathological department of the museum by the Regius Professor of Medicine or his Deputy. Practical Pharmacy is taught in the Infirmary Dispensary. The whole course of study at the museum and infirmary combined is intended for students until they have passed the Second Conjoint Examination or the First Oxford M.B.

UNIVERSITY COLLEGE, SHEFFIELD—DEPARTMENT OF MEDICINE.—The Medical School has recently been incorporated by Royal Charter with Firth College and the Sheffield Technical School, under the title of University College, Sheffield. An entrance scholarship of the value of £110 will be awarded to the best candidate (if of sufficient merit) in Mathematics, Elementary Physics, Inorganic Chemistry, Latin, and English. The examination will be held at the College on Sept. 23rd and 24th. Applications to be sent to the Dean not later than Sept. 16th. Prizes for Clinical Medicine and Surgery of 10 guineas are offered by the Clinical Committee. Prizes in books and certificates are awarded annually. The medical school is provided with dissecting-room, physiological laboratory, museum, library, and class-rooms. The physiological department has recently been entirely reconstructed and equipped in memory of the late President of the school, Mr. Wm. F. Favell, and will in future be called the Favell Laboratory. The department consists of a lecture and demonstration theatre, preparing-room, and galvanometer room. In addition to the usual fittings the theatre is provided with a projection lantern microscope for the demonstration of microscopic slides. Each student has his own laboratory bench, with gas, water, electric light, and the requisite apparatus. The department is lighted throughout by electricity. The course of lectures and instruction is adapted to meet the requirements of the various examining bodies. The Sheffield Royal Infirmary contains 240 beds, including Ophthalmic and Dermatological departments, a museum of Pathology, library, and post-mortem theatre, with microscopes and all the appliances for clinical research. New Ophthalmic wards have recently been erected. The Sheffield Royal Hospital contains 125 beds and a Dental department, and is recognised by the examining bodies. Perpetual fee for hospital practice £45 in one payment; or by two instalments: £26 on entering for hospital practice, and 22 guineas within twelve months afterwards. Composition fee for lectures and practical courses 60 guineas; or in two instalments: 35 guineas at commencement of medical study, 30 guineas at beginning of the second year. Students are also admitted to the practice of the Jessop Hospital for Diseases of Women, to the Borough Fever Hospitals, and the South Yorkshire Asylum.

JESSOP HOSPITAL FOR WOMEN, Gell-street, Sheffield.—The hospital is devoted to Diseases peculiar to Women. There is also an Obstetric Department for the admission of a small number of cases. A staff of midwives connected with the hospital attend lying-in women at their own homes, and, in case of need, are assisted by the members of the medical staff. Out-patients are attended daily. Students can attend the practice of the hospital and be supplied with cases of midwifery. Communications should be addressed to the Secretary, York Chambers, York-street, Sheffield.

DEVON AND EXETER HOSPITAL, Exeter.—Medical and Surgical Staff: Consulting Physician: Dr. Drake. Physicians: Drs. H. Davy, Arthur G. Blomfield, and Wm. Gordon. Consulting Surgeons: Messrs. A. J. Cumming, T. W. Caird, and James Bankart. Surgeons: Messrs. J. D. Harris, E. J. Domville, Charles E. Bell, and A. C. Roper. House Surgeon: Mr. Henry Andrew. Assistant House Surgeon: Mr. W. Ashford. The hospital contains 218 beds (including special children's wards), and has a good library, museum, dissecting room and post-mortem room. Attendance on the practice of this hospital qualifies for all the examining boards. Arrangements can be made by which students can attend Midwifery. There is also a Nurses' Home attached to the Hospital. For further particulars as to fees &c. apply to the House Surgeon. A new wing has lately been added.

WEST OF ENGLAND EYE INFIRMARY, Exeter.—Physician: Dr. William Gordon. Surgical Staff: Messrs. Bankart and Tosswill. Assistant Surgeon and Registrar: Mr. Roper. Secretary: Ernest W. Toby. The infirmary contains fifty beds. Students of the Exeter Hospital can attend the practice of the Eye Infirmary. Patients for the year ending Michaelmas, 1896, 2818. Total number of patients since the opening of the Infirmary in 1808, 90,359. Days of admission: Mondays, Tuesdays, and Fridays, at 11 A.M.

KENT AND CANTERBURY GENERAL HOSPITAL.—Opened for the reception of patients April 26th, 1793. 56,553 in-patients and 100,589 out-patients have been admitted since the hospital was opened. The hospital contains 106 beds. Pupils of the staff are admitted to the practice of the hospital, and have the use of the library of the East Kent and Canterbury Medical Society for £7 7s. Operation day, Thursday, 11 A.M. Physician: Dr. Henry Alex. Gogarty. Consulting Surgeon: Mr. James Reid. Surgeons: Messrs. Frank Wacher, T. Whitehead Reid, J. Greasley, and Sydney Wacher. Dentist: Mr. R. S. N. Faro. House Surgeon: Mr. J. H. Joyce. Assistant House Surgeon: Mr. E. C. Frend. Secretary: Mr. Arthur J. Lancaster. Over 700 in-patients, 2000 out-patients and casualties, and 357 dental cases are attended in a year.

LIVERPOOL NORTHERN HOSPITAL (160 beds).—There is a special ward for the treatment of children. Clinical instruction is regularly given by the physicians and surgeons during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fee. Consulting Surgeons: Mr. W. H. Manifold and Dr. W. Macfie Campbell. Physicians: Dr. E. H. Dickinson, M.A.; Dr. Bushby. Surgeons: Messrs. Chauncy Pozey, Damer Harrisson, and A. H. Wilson. Fees for hospital attendance: Perpetual, £26 5s.; one year, £10 10s.; six months, £7 7s.; three months, £4 4s.; Practical Pharmacy, £2 2s. Students can enter to the medical or the surgical practice separately on payment of half the above fees. The foundation-stone of a new hospital of not less than 200 beds has been laid during the past year, in

Digitized by Google

which there will be every facility for clinical teaching and accommodation for resident pupils.

LIVERPOOL ROYAL SOUTHERN HOSPITAL (CLINICAL SCHOOLS).—Honorary Consulting Surgeon: Mr. Robert Hamilton. Honorary Physicians: Drs. John Cameron, Wm. Carter, and Wm. Williams. Honorary Surgeons: Messrs. Henry G. Rawdon, Wm. Alexander, and Robert Jones. Consulting Pathologist: Dr. R. W. Boyce, Professor of Pathology, Liverpool University College. Lecturer on Practical Medicine: Dr. C. J. Macalister. Surgical Tutor: Mr. W. H. C. Davey. Pathologist: Dr. F. H. Barendt. Medical Tutor and Bacteriologist: Dr. H. R. Jones. Honorary Ophthalmic Surgeon: Mr. R. Williams. Honorary Aural Surgeon: Mr. C. G. Lee. Honorary Laryngologist: Dr. W. Permewan. Demonstrator of Roentgen Rays: Dr. C. Thurston Holland. Honorary Dental Surgeon: Mr. J. Royston. House Surgeon: Dr. J. A. Craig. Junior House Surgeons: Dr. Barlow and Dr. Kewley. The hospital is situated within convenient distance of the School of Medicine and contains 200 beds. There are special wards for accidents and Diseases of Children, and there are also beds appropriated to the Diseases of Women. Clinical teaching is given in the hospital, and arrangements have been made to render it both thorough and systematic. The members of the staff visit the wards daily, and clinical lectures are given every week. Tutorial classes are also held each day at which the junior students are instructed in the methods of diagnosis and the seniors are prepared for their final examinations. The pathological department has a good laboratory attached in which the students receive practical instruction. Recently a bacteriological laboratory has been added, where students are able to obtain a practical knowledge of bacteriology in relation to medicine. In connexion with the hospital a course of instruction for gentlemen desirous of obtaining a Diploma in Public Health is given, and with this object a chemical laboratory under Mr. Herbert Davies, M.A. Camb., B.Sc. Lond., has been opened. In addition to the usual clinical and post-mortem clerkships, which are open to all students, the resident post of Ambulance Officer is awarded every three months to the student whom the board may consider most suited to hold it. A Scholarship of £20 is competed for annually, which has attached to it some clinical and pathological duties; and three prizes of £5 each are yearly offered for the best series of clinical reports. Fees: Perpetual £26 5*s*.; one year £10 10*s*.; six months £7 7*s*.; three months £4 4*s*. A limited number of resident pupils can be received. Terms (exclusive of fees for Hospital Practice), £15 15*s*. per quarter. The practice of the hospital is recognised by all examining bodies. For further particulars apply to the Dean, Mr. Robert Jones, 11, Nelson-street, Liverpool.

ROYAL INFIRMARY, Liverpool.—The buildings of the new Royal Infirmary were completed and occupied in 1890. They stand on the old site, adjacent to the college, but enlarged by the purchase of a fine frontage in Pembroke-place and of the street known as Pembroke-gardens. Externally, they form a handsome and imposing group of buildings, the general arrangement of which may be gathered from the plan at the beginning of the prospectus. Every available open-air space has been taken advantage of to secure good airing grounds for the patients, and the beauty of the buildings has been not a little enhanced by the numerous balconies, colonnades, and flat roofs adapted to the same purpose for both patients and resident staff. Internally, no point in modern sanitary science has been omitted. There are 295 beds exclusive of the Lock Hospital. The wards—some parallelograms, some circular—have floors of waxed oak blocks laid on an iron and cement substratum. Three operating theatres and a clinical lecture theatre have been provided. There is an electrical room, and provision for special kinds of baths. The out-patient department comprises rooms for the treatment and study of minor medical and surgical maladies, for diseases of the eye, skin, larynx, nose, and teeth, as well as a gynæcological department. There is also a Lock Hospital. A room has been allotted to the clinical tutors, in which they may keep their records, whilst each surgeon and physician has a private room in connexion with his wards, where his dressers and clerks may write up and tabulate cases and investigate morbid products. The pathological department, which is daily becoming of more importance in medical education, has had much pains expended upon it, so as to give proper facilities for the study of morbid anatomy. It is hoped that the facilities for clinical work will be such as not merely to enable the present students to learn the practical parts of their profession thoroughly, but to attract students from over-crowded institutions where the number of pupils is far in excess of the opportunities for the bedside study of disease. In no hospital in the country are the resident physicians and surgeons so comfortably lodged. Each is provided with a bedroom and a private sitting-room in addition to the music-room and dining-room, where all the seven residents meet in common. James Burr, M.D., Secretary of Medical Board, 72, Rodney-street, Liverpool.

NORFOLK AND NORWICH HOSPITAL (220 beds).—Fees: £10 10*s*. for six months', £15 15*s*. for twelve months' medical and surgical practice. Pupils: resident and non-resident. Consulting Physicians: Sir P. Eade, M.D., and Sir Frederic Bateman, M.D. Consulting Surgeon: Mr. W. Cadge, F.R.C.S. Physicians: Dr. Barton and Dr. Burton-Fanning. Surgeons: Mr. Williams, Dr. Beverley, and Mr. H. S. Robinson. Assistant Surgeons: Mr. S. H. Burton and Mr. D. D. Day. Dental Surgeon: Mr. R. Wentworth White. House Surgeon: Mr. H. A. Ballance. House Physician: Mr. S. H. Long. Secretary: Mr. Poole Gabbett.

NORTHAMPTON GENERAL INFIRMARY (established 1743; rebuilt 1793).—The number of beds is 160. Out-pupils are received, and have every opportunity of acquiring a practical knowledge of their profession. Instruction is also given in Anatomy and Materia Medica and Practical Pharmacy. Non-resident pupils are taken at a fee of £10 10*s*.

NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill, Stoke-on-Trent.—The New Infirmary, opened in 1869, is built on the pavilion plan, has accommodation for over 200 patients, including Children's wards, special Ovarian wards, and a special department for the treatment of Diseases of the Eye. In-patients last year, 1957; out-patients, 9822. The attendance of pupils at this infirmary is duly recognised by all the examining boards; and there are unusual facilities for acquiring a practical knowledge of the profession. Physician: Dr. A. M. McAldowie. Surgeons: Messrs. J. Alcock and W. D. Spanton. Ophthalmic Surgeon: Mr. Herbert Folker. Assistant Ophthalmic Surgeon: Mr. J. F. Arlidge. Assistant Physicians: Dr. S. King Alcock and Mr. H. Nicholls. Assistant Surgeons: Drs. G. S. Hatton and W. Hind. Dental Surgeon: Mr. A. Baines. House Physician: Dr. William C. Allardice. House Surgeon: Mr. John L. Sawers. Secretary: Mr. R. Hordley, Hartshill, Stoke-on-Trent.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL (founded 1845; beds, 230).—A preparatory school of Medicine and Surgery. The pupils have the advantage of seeing the whole of the practice of the physicians and surgeons, and are trained in clinical work by the medical and surgical staff. The attendance of pupils at this hospital is recognised by all the examining boards. Operations are performed every Thursday at 11 o'clock.

SUSSEX COUNTY HOSPITAL (190 beds).—During the year 1896, 1710 in-patients have been treated. The total number of out-patient attendances on the books during 1896 was 30,847. This hospital affords ample facilities for students, possessing a large out-patient department, a library, and a well-appointed museum. The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years on payment in advance of such a fee, not exceeding 20 guineas, as the Committee of Management shall direct.

MANCHESTER GENERAL HOSPITAL FOR SICK CHILDREN, Pendlebury and Gartside-street.—The hospital contains 140 beds, including 28 for scarlet fever. The medical staff visit the hospital daily at 10 A.M. Clinical instruction is given by the medical staff at the Hospital and Dispensary. Out-patients are seen daily at 9 A.M. at the Dispensary, Gartside-street, Manchester. Physicians: Drs. Ashby and Hutton. Surgeon: Mr. G. A. Wright. Assistant Surgeon: Mr. Joseph Collier. Resident Medical Officers: H. E. Izard, M.R.C.S., and A. H. Burgess, M.B. Medical Officer at the Dispensary: Mr. J. Hepworth, M.R.C.S. During 1896 there were 1286 in-patients, and 11,502 out-patients were under treatment at the Dispensary.

THE MANCHESTER CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, Cheetham-hill-road, Manchester.—The hospital is situated near the centre of the town and contains 70 beds. Out-patients are seen daily at 9.30 A.M. and the wards are visited at 11 A.M. The hospital practice is open free to students and practitioners both in the out-patient department and in the wards during the hours of the medical staff.

Applications to be made to the secretary, Mr. H. Teague, Barton Arcade, Manchester.

SCOTLAND.

MEDICAL SCHOOLS WITH FULL CURRICULUM.[1]

EDINBURGH.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, Edinburgh.—The number of students varies much in the classes and subjects. It is within the limit to say that about 1000 students avail themselves each year of the opportunity of attending the school. The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards. In accordance with the recent Statutes of the University of Edinburgh one-half of the qualifying classes required for graduation may be attended in this school. The regulations require that the fee for any class, taken for Edinburgh University graduation, shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

In accordance with the statutes of the University of Edinburgh, one-half of the qualifying classes required for graduation may be attended in this school, in addition to the class of Practical Materia Medica and the classes of Clinical Medicine and Clinical Surgery. The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University. The whole education required for graduation at the University of London may be taken in this school.

The following Order of Study is recommended as a guide to the student for a five years' course, though not enjoined :—First Year: Biology, Physics, Anatomy, Practical Anatomy, Chemistry, and Practical or Analytical Chemistry. Second Year: Anatomy, Practical Anatomy, Physiology, Practical Physiology, Surgery, and Materia Medica—the last either in this or the Third Year—and Hospital. Third Year: Practice of Medicine, Clinical Surgery, Practical Pharmacy, Clinical Medicine, Pathology, and Hospital. Fourth Year: Surgery or Clinical Surgery, Midwifery and Diseases of Women and Children, Practice of Medicine or Clinical Medicine, Medical Jurisprudence, Practical Midwifery, Operative Surgery, and Hospital. Fifth Year: Classes on Special Subjects, Hospital, and Dispensary Practice.

The appointment of Resident Physician to the wards in the Royal Infirmary under the care of the Ordinary Physicians is open to those members of their clinical class who have clerked in their wards for at least six months. Six Residentships are appointed during the year for a period of six months each. Resident Surgeons are also appointed by the Ordinary Surgeons to the Hospital. In all respects the students are taught under regulations similar to those at the University of Edinburgh and the other Universities of Scotland, and they receive similar certificates at the close of each session. Moreover, the University and College authorities in Edinburgh and the governing board of the school call upon each recognised lecturer to supply them at the close of each session with a statement giving the number of students attending the class, the number of lectures or prelections delivered during the session, the class examinations held, and the general mode of conducting the class. The courses on special non-qualifying subjects have for the last quarter of a century formed a marked feature of the school. Indeed, such medical subjects could be studied in Edinburgh only in this school until lately, when the University of Edinburgh appointed from the school lecturers on Diseases of the Eye, Insanity, and Diseases of Children to take charge of classes intra-murally. A list of the classes and lecturers will be found below. Special courses of instruction for dental students and for women are also included in the curriculum of this school.

Lecturers and fees.—Winter Session: Anatomy, Practical Anatomy, and Demonstrations, Drs. Ryland Whitaker and R. J. A. Berry (£3 5*s.* and £4 4*s.*); Chemistry (Practical, &c.), Dr. S. Macadam, Mr. King, Mr. I. Macadam, and Drs. Aitken and Readman*; Physiology (Institutes of Medicine), Dr. Noël Paton (£3 5*s.*); General Pathology, &c., Drs. Bruce, Russell, and Leith (£3 5*s.*); Botany, Mr. A. N. McAlpine†; Practice of Physic, Drs. Wyllie, James, Affleck, Bramwell, Gibson, Philip, and Graham Brown (£3 5*s.*); Surgery. Messrs. Caird, Hodsdon, Shaw Maclaren, Thomson, and Wallace (£3 5*s.*); Materia Medica, &c., Drs. Craig† and Lockhart Gillespie (£3 5*s.*); Midwifery, &c., Drs. Hart, Murray, and Haultain (£3 5*s.*); Medical Jurisprudence, &c., Dr. Littlejohn (£3 5*s.*); Natural History, Mr. J. Arthur Thomson† (£3 5*s*); Natural Philosophy, Dr. Turner and Mr. Purvis (£3 5*s.*); Hospital Practice (Edinburgh Royal Infirmary): Physicians, Drs. Affleck, Smart, James, and Croom; Surgeons, Messrs. Duncan and Miller, Drs. Maclaren and MacGillivray (perpetual ticket, £12 12*s.*); Clinical Medicine, Drs. Wyllie, Affleck, Smart, James, and Croom (Diseases of Women) (£3 5*s.*); Clinical Surgery, Mr. Duncan, Mr. Miller, Dr. Maclaren, and Dr. Macgillivray (£3 5*s.*); Diseases of Children, Mr. Joseph Bell,† Drs. Burn-Murdoch,† Thomson,† Ballantine,† and Dunlop† (£2 2*s.*); Diseases of the Skin, Drs. Jamieson† and Stirling† (£2 2*s.*); Diseases of the Chest, Dr. Philip† (£2 2*s.*); Vaccination, Drs. Husband,† Buist,† and Cadell (£1 1*s.*); Diseases of Ear, Nose, and Throat, Drs. Kirk, Duncanson,† and McBride† (£2 2*s.*); Diseases of the Eye, Dr. G. Mackay† and Dr. Sym† (£2 2*s.*); Gynæcology. Drs. Croom (Systematic), Brewis (Clinical), and Berry Hart (Advanced) (£2 2*s.*); Diseases of the Tropics and Climatology, Dr. Felkin† (£2 2*s.*). Summer Session: Practical Anatomy and Demonstrations, Drs. Ryland Whitaker and R. J. A. Berry (£2 2*s.*); Practical Physiology, Dr. Paton (£3 3*s.*); Biology, Messrs. Thomson and Turnbull‡ (£3 3*s.*); Botany, Messrs. McAlpine and Turnbull; Practical Chemistry and Analytical Chemistry, Dr. S. Macadam, Messrs. King, I. Macadam, Drs. Aitken and Readman§; Diseases of the Eye, Dr. Mackay‡ (£2 2*s.*); Diseases of the Skin, Drs. Allan Jamieson and Stirling (£2 2*s.*); Medical Psychology and Insanity. Drs. Tuke and Macpherson (£1 1*s.*); Gynæcology, Drs. Brewis and Haultain (£2 2*s.*); Midwifery, Drs. Croom, Hart, Barbour, and Ferguson (£3 5*s.*); Operative Surgery, Messrs. Caird, Hodsdon, Shaw, McLaren, and Alexis Thomson (£3 3*s.*); Practical Pathology, Drs. Bruce, Russell, and Leith (£3 3*s.*); Physics, Dr. Turner‡ (£3 3*s.*); Practical Medicine and Physical Diagnosis, Dr. James (£3 3*s.*); Practice of Medicine, Drs. Bramwell, Gibson, and Philip (£3 3*s.*); Medical Electricity, &c., Dr. Turner (£2 2*s.*); Diseases of the Circulation, Dr. Gibson (£2 2*s.*).

Special Classes for Women, Winter Session: Practical Anatomy and Demonstrations, Drs. Ryland Whitaker and Hardie (£4 4*s.*); Chemistry (Lectures and Practical), Mr. Ivison Macadam and Dr. Aitken (£3 5*s.* and £3 3*s.*); Practice of Physic, Drs. Philip and Graham Brown (£3 5*s.*); Surgery, Mr. Thomson and Mr. McLaren (£3 5*s.*); General Pathology, Dr. Russell (£3 5*s.*); Physiology (Institutes of Medicine), Dr. Noël Paton (£3 5*s.*); Practical Pathology, Dr. Bruce, &c. (£3 5*s.*); Materia Medica, &c., Dr. Craig (£3 5*s.*); Clinical Medicine, Dr. Bramwell, Royal Infirmary (£3 5*s.*); Clinical Surgery, Royal Infirmary (£3 5*s.*); Physics, Dr. Dawson Turner (£3 3*s.*); Biology, Mr. Thomson and Mr. Turnbull (£3 3*s.*); Diseases of Children, Mr. Bell, Dr. Burn-Murdoch, and Dr. Cumming (£2 2*s.*); Vaccination, Dr. Husband and Mr. Cadell £1 1*s.*); Diseases of the Tropics and Climatology, Dr. Felkin (£2 2*s.*); Practical Gynæcology, Dr. Brewis (£2 2*s.*). Summer Session: Practical Anatomy, Dr. Ryland Whitaker and Mr. Hardie (£2 2*s.*); Practical Chemistry, Mr. Ivison Macadam and Dr. Aitken (£3 3*s.*); Materia Medica, &c., Dr. Craig (£3 3*s.*); Operative Surgery and Surgical Anatomy, Mr. Alexis Thomson and Mr. McLaren (£3 3*s.*); Materia Medica and Therapeutics, vacant (£3 3*s.*); Midwifery and Diseases of Women, Drs. Sophia Jex-Blake and R. Milne Murray (£3 5*s.*); Medical Jurisprudence and Public Health, Dr. Harvey Littlejohn (£3 5*s.*); Clinical Medicine and Clinical Surgery, Royal Infirmary (£3 5*s.*); Practical Physiology and Histology, Dr. Paton (£3 3*s.*); Practical Pathology, Dr. Russell (£3 3*s.*); Biology, Mr. Arthur Thomson and Mr. Turnbull (£3 3*s.*); Physics, Dr. Dawson Turner (£3 3*s.*); Diseases of Children, Mr. Bell, Dr. Burn-Murdoch, and Dr. Cumming (£2 2*s.*); Ophthalmology, Dr. Mackay (£2 2*s.*); Insanity, Dr. Tuke and Dr. Macpherson (£2 2*s.*); Practical Gynæcology, Dr. Brewis (£2 2*s.*).

The minimum cost of the education in this School

[1] For Scholarships see p. 501, et seq.

Digitized by Google

of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, including the fees for the Joint Examinations, is about £115, which is payable by instalments during the period of study.

Further particulars regarding the school, also its calendar, may be had on application to Mr. R. N. Ramsay, the Secretary, 24, Forrest-road, Edinburgh.

* Lectures, £3 5*s.*; Practical, £3 3*s.*; Analytical, £2 a month, or £5 for three months. † Also in Summer Session. ‡ Also in Winter Session. § Practical, £3 3*s.*; Analytical, £2 a month, or £5 for three months.

N.B.—Where two or more lecturers appear as teaching the same subjects their lectures are not conjoined, but each gives an independent course.

GLASGOW.

ANDERSON'S COLLEGE MEDICAL SCHOOL, Glasgow.—This medical school was founded in the year 1800. It has given twelve professors to the University of Glasgow, of whom three at present hold office. The following courses are given, which qualify for all the licensing boards and for the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions):—In winter: Anatomy, Professor A. M. Buchanan, M.A., M.D.; Chemistry, Professor J. Robertson Watson, M.A.; Physics, Professor Peter Bennett; Zoology, Professor Geo. Bell Todd, M.B.; Physiology (vacant); Surgery, Professor T. Kennedy Dalziel, M.B.; Practice of Medicine, Professor Samson Gemmell, M.D.; Midwifery and Diseases of Children, Professor John Edgar, M.A., B.Sc., M.D.; Materia Medica, Professor R. Barclay Ness, M.A., M.B.; Botany, Professor B. G. Cormack, M.A., B.Sc.; Ophthalmic Medicine and Surgery, T. Spence Meighan, M.D.; Aural Surgery, James Erskine, M.A., M.B.; Diseases of Throat and Nose, John Macintyre, M.B.; Hygiene and Public Health, In summer: Anatomy, Practical Anatomy and Osteology, Practical Chemistry, Physics, Zoology, Practical Materia Medica and Pharmacy, Practical Physiology, Operative Surgery, Medical Jurisprudence; Botany; Ophthalmic Medicine and Surgery; Mental Diseases; Hygiene and Public Health, and Aural Surgery. The Chemical Laboratory is open daily from 10 to 6. The Dissecting-room is open in winter from 9 A.M. to 6 P.M., and in summer from 6 A.M. to 6 P.M. The students are assisted in their dissections by the Professor and Demonstrators, by whom frequent examinations and demonstrations on the parts dissected are conducted. The supply of subjects for dissection is ample, and students are consequently provided with parts as soon as they may be ready for them. The Dissecting-room is provided with a complete series of dissected specimens, mounted in plaster-of-Paris, illustrating the anatomy of the human body. Candidates for the licence in Dental Surgery can obtain the full medical curriculum in Anatomy, Chemistry, Physiology, Surgery, Practice of Medicine, and Materia Medica. The courses special to Dentistry are conducted at the Glasgow Dental Hospital and School.

The new buildings are situated in Dumbarton-road, immediately to the west of the entrance to the Western Infirmary, within two minutes' walk of it, and four minutes' walk of the University. Extensive accommodation is provided for Practical Anatomy, Practical Chemistry, Practical Physiology, Practical Pharmacy, Public Health, and Operative Surgery. There are also provided a large library and reading-room and a students' recreation-room.

Fees.—For each of the above courses of Lectures (Anatomy, Chemistry, Botany, Zoology, and Mental Diseases excepted), first session. £2 2*s.*; second session, £1 1*s.* Anatomy Class Fees: Winter, first session (including Practical Anatomy), £4 4*s.*; second session (including Practical Anatomy), £4 4*s.*; third session, £2 2*s.* To those who have had the necessary courses of Practical Anatomy the fee will be £1 1*s.* Summer, Lectures and Practical Anatomy, £2 12*s.* 6*d.*; Lectures alone, £1 11*s.* 6*d.*; Practical Anatomy alone, £1 1*s.*; Osteology and Practical Anatomy, £2 12*s.* 6*d.*; Osteology alone, £1 11*s.* 6*d.* Chemistry Fees: First course, £2 2*s.*; second course, £2 2*s.* Practical Materia Medica and Pharmacy. Fees.—First course, £2 2*s.* Second course, £2 2*s.* Botany fee, £1 11*s.* 6*d.* Zoology fee, £1 11*s.* 6*d.* Mental Diseases, £1 1*s.* Matriculation Fees: Winter, 10*s.* to those taking out two or more classes; 5*s.* to those taking out only one class. The fee of 10*s.* represents a combined fee for the winter and summer sessions. Summer, 5s., except to those who have paid a fee of 10*s.* for the Winter Session. Students who have attended classes at other schools, and who desire to pursue their studies at Anderson's College Medical School, will be admitted to such classes as they may have attended elsewhere at the reduced fees.

Royal Infirmary.—Fees: Hospital Practice and Clinical Instruction, first year, £10 10*s.*; second year, £10 10*s.*; afterwards free. Six months, £6 6*s.*; three months, £4 4*s.*; Pathology, both courses, £3 3*s.* Vaccination Fee, £1 1*s.*

Western Infirmary.—Fees: Hospital Practice and Clinical Instruction, first year, £10 10*s.*; second year, £10 10*s.*; afterwards free. Six months, £7 7*s*; three months, £4 4*s.* Pathology, first course, £3 3*s.*; second course, £2 2*s.* Practical Pathology, first course, £3 3*s.*, second course, £2 2*s.* Vaccination Fee, £1 1*s.*

Eye Infirmary.—Fee: Hospital Practice and Clinical instruction, six months, £1 1*s.*

Certificates of attendance on the lectures at Anderson's College Medical School are received by the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions); by the Royal Colleges of Physicians of London and Edinburgh; by the Royal Colleges of Surgeons, England, Edinburgh, and Ireland; by the Royal College of Physicians of Ireland; by the Faculty of Physicians and Surgeons of Glasgow; by the Society of Apothecaries, London; and by the Army, Navy, and East India Boards. Communications relating to the Medical School to be addressed to the Secretary of the Medical Faculty, Professor A. M. Buchanan, M.A., M.D., Anderson's College Medical School, Dumbarton-road, Partick, Glasgow. Communications relating to the Preliminary Examination in General Education to be addressed to Mr. Alexander Mackay, LL.D., Educational Institute Office, 40, Princes-street, Edinburgh. Communications relating to the Triple Qualification to be addressed to Mr. Alexander Duncan, B.A., Faculty Hall, 242, St. Vincent-street, Glasgow. Communications relating to the Dental School to be addressed to Mr. D. M. Alexander, 97, West Regent-street, Glasgow.

At *Anderson's College Medical School* Professorships of Physics and Zoology and a Lectureship on Mental Diseases have been recently instituted. Lectures on Physics and on Zoology are delivered in winter and summer, and lectures on Mental Diseases in summer, the fee for Mental Diseases being £1 1*s.* The Kerr Bursary in Anatomy (value £10) is open to students of the Junior Anatomy Class during Winter Session 1897-98.

ST. MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY.—This College was incorporated in 1889. The Glasgow Royal Infirmary was founded in 1791. The Faculty of Medicine of the College occupies new buildings erected for the purposes of a medical school, adjoining and communicating with the Royal Infirmary. The Laboratories, Museums, and Lecture-rooms are equipped and adapted to modern scientific requirements. Recent additions consist of Public Health, Practical Zoology, and Bacteriological Laboratories. The Royal Infirmary, which is at the service of the College for the purpose of clinical and practical instruction, is one of the largest general and special hospitals in the kingdom. It has nearly 600 beds, and will almost immediately have considerably over 600. It has special wards for Diseases Peculiar to Women, for Venereal Diseases, Erysipelas, Burns, and Diseases of the Throat and Nose. At the Dispensary special advice and treatment are given in diseases of the Eye, Ear, Teeth, and Skin, Women, Throat and Nose, in addition to the large and varied number of ordinary medical and surgical cases—over 46,000 per annum—which in a great industrial centre daily require attention. Students of the College and Hospital get the benefit of dispensary experience free of charge. All appointments are open. There are five Physicians' and seven Surgeons' Assistants, who board in the hospital free of charge and act in the capacity of House Physicians and House Surgeons. These appointments are made for six months, and are open to gentlemen who have a legal qualification in Medicine or Surgery, and preference is given to the students of this College and Hospital. Clerks and Dressers are appointed by the Physicians and Surgeons. From the large number of cases of acute disease and accidents of varied character received into this hospital these appointments are very valuable. In the Pathological Department assistants are also appointed. The session will open with an address on Wednesday, Oct. 20th, at the College buildings.

OPERATIVE SURGERY	Dr. Pringle	2 2 0
PRACTICAL PATHOLOGY	Dr. Workman	3 3 0

West Regent-street having been amalgamated with the Royal Infirmary the usefulness of this department is very much increased, and greater opportunities are afforded to students for the practical study of Diseases of the Eye. Dr. Ramsay, the ophthalmic surgeon, attends the Royal Infirmary every Monday, Wednesday, and Friday at 12 noon, and daily at the Institution in West Regent-street from 1 to 2 o'clock. Students can attend both without payment of any additional fee. Lectures are delivered twice a week during the winter session. Fee for the course, £2 2*s*.

The fee for each class is £2 2*s*., except for Anatomy, which is £4 4*s*., Pathology £4 4*s*., Zoology £4 4*s*., Botany £3 3*s*., Practical Physiology, £3 3*s*., and for Physics, which is £2 4*s*. 6d., and certain extra classes, for which the fee is £1 1*s*. The hospital fee (including clinical lectures) is £21 for a perpetual ticket. The classes in St. Mungo's College and in the Glasgow Royal Infirmary are for male students exclusively. Further particulars can be obtained in the Calendar of the College (price 1*s*.), which can be obtained on application to the Dean, 86, Castle-street, Glasgow. Remittance should accompany application.

GLASGOW WESTERN MEDICAL SCHOOL.—This School is situated in University-avenue, close to the University and Western Infirmary, in which latter students obtain their Hospital Practice and Clinical Lectures. Lectures and Demonstrations are given on Chemistry, on Anatomy, on Surgery, on Physiology, on Midwifery and Gynæcology, and on the Eye.

Class Fees.—For each course of Lectures the fee is £2 2*s*., or in some cases £1 1*s*. There is no matriculation fee.

QUEEN MARGARET COLLEGE, University of Glasgow.—Queen Margaret College was founded in 1883 by the Glasgow Association for the Higher Education of Women (instituted in 1877), and handsome buildings and grounds near the University were presented to the College in 1884 by Mrs. John Elder. In 1890 a School of Medicine for women was added to its Arts Faculty. In 1892, when the Universities Commissioners issued an ordinance empowering the Scottish University Courts to make provision for the instruction of women, the Council of the College and Mrs. Elder transferred to the University the College, its buildings, grounds, and endowments, on condition that these should be devoted to the maintenance of University classes for women only. The College then became the women's department of the University of Glasgow; its classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men. They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College. The number of students enrolled in session 1896-7 was 249, of whom 82 were studying medicine, and the rest arts or science. The School of Medicine is a special feature of the College and gives full preparation for the medical degrees of the University. In July, 1894, for the first time in the history of any Scottish university, women students graduated in medicine at the "capping" in Glasgow University. Excellent facilities for clinical work are given in the Royal Infirmary and other hospitals. By a gift of £5000 lately granted for the purpose by the Bellahouston Trust the University Court was enabled to add to the College a large new building for the study of Anatomy and Physiology, which was opened in October, 1895. The Arthur Scholarship is open every third year to students of first year entered the October previously to the award; the George Grant Bursary is held by a woman student, and there are other Bursaries open in Arts as well as in Medicine; and the Universities Commissioners have issued an ordinance making regulations for the admission of women to certain University bursaries, scholarships, and fellowships. A house of residence for the students of the College coming from a distance was opened by the Queen Margaret Hall Co., Limited, in October of 1894.

DUNDEE.

UNIVERSITY COLLEGE, Dundee (University of St. Andrews).—The classes of this College qualify for graduation in the University of St. Andrews and are recognised by the other Scotch Universities; they also qualify for the degrees of the University of London and the Royal University of Ireland and for the Licences of the Royal Colleges. Equipment is provided for the first three years of the medical curriculum; and of recent years the laboratory accommodation in the departments of Chemistry, Botany, Zoology, Anatomy, and Physiology has been largely added to. The Royal Infirmary of Dundee contains about 300 beds, and the clinical instruction and hospital attendance in its wards are recognised by the various degree-giving and licensing bodies. The teaching staff of the school has lately been increased by the appointment of Lecturers on Medical Jurisprudence and Public Health, Mental Diseases, and Ophthalmology, and in these departments, as also in Operative Surgery and Practical Obstetrics, special facilities are offered to senior students.

Scholarships:—First year: (*a*) Three Armitstead Scholarships of £20 each, tenable for one year. (These Scholarships were founded and endowed in 1883 by George Armitstead, Esq., M.P.) (*b*) Three Scholarships of £15 each, tenable for one year. Second year: Three Armitstead Scholarships of £20 each, tenable for one year, to be awarded to day students entering upon their second year. Candidates must have attended not less than two regular courses at the College during the year immediately preceding the competition. (*c*) Bute Bursary, founded in 1893 by the Most Honourable the Marquess of Bute, K.T.; this bursary consists of the free proceeds of £1000. (*d*) Two bursaries of the annual value of £25, and tenable for three years, either "at University College, Dundee, or at any Scottish University."

Fees.—Chemistry, £3 3*s*.; Prof. James Walker, D.Sc. Practical Chemistry: Winter £3 3*s*., Summer £2 2*s*.; Prof. James Walker, D.Sc. Physics: Winter £3 3*s*., Prof. Kuenen, Ph.D., M.A. Zoology, £3 3*s*., Prof. D'Arcy W. Thompson, M.A. Botany, £3 3*s*., Prof. Geddes. Anatomy, £3 3*s*.; Prof. Yule Mackay, M.D. Practical Anatomy: Winter £3 3*s*., Summer £2 2*s*.; Prof. Yule Mackay, M.D. Physiology, £3 3*s*.; Prof. E. W. Reid, B.A., M.B. MacEwan and Greig. Hospital fee, £2 2s.; Dispensary, £2 2s. The Lectures and Classes for the winter session will commence on Tuesday, Oct. 5th.

ROYAL INFIRMARY.—The infirmary contains 286 beds, including special wards for the Diseases of Children, Eye, and Lock cases. In addition, there were during last year 7905 out-patients and 6366 home patients. The Royal Infirmary offers exceptional facilities for practical work to students. Three qualified Resident Assistants and Clinical and Pathological Assistants are appointed as vacancies occur. Appointments: Three qualified Resident Medical Assistants are appointed annually. Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological department. There is in connexion with the hospital course a class of Minor Surgery and Bandaging, conducted by the Assistant Surgeons, and a class of Practical Pharmacy and Materia Medica held at the Dispensary. Full information can be obtained from Dr. Nathan Raw, Medical Superintendent.

ROYAL ASYLUM.—Clinical instruction is given at the Royal Asylum. Appointments: One paid qualified Resident Assistant and two unpaid Resident Clinical Assistants.

ABERDEEN.

ABERDEEN ROYAL LUNATIC ASYLUM.—Contains, with hospital attached to main institution and Agricultural Branch, about 820 beds. Medical Superintendent: Dr. William Reid. Assistant Physicians: Drs. C. Angus and W. R. Matthews. Joint Secretaries: Mr. W. Carnie and Charles M. Brown. Clinical instruction is given to students during three months in summer.

ABERDEEN ROYAL INFIRMARY.—Contains about 200 beds. Consulting Physicians: Drs. P. Blaikie Smith and James Rodger. Physicians: Drs. Angus Fraser, Professor Finlay, and George M. Edmond. Assistant Physicians: Drs. John Gordon, A. H. Lister, and Ashley W. Mackintosh. Consulting Surgeon: Dr. J. C. O. Will. Surgeons: Professor A. Ogston, Drs. R. J. Garden and J. McK. Booth. Assistant Surgeons: Drs. J. S. Riddell, W. Sinclair, and J. Marnoch. Ophthalmic Surgeon: Dr. C. H. Usher. Pathologist: Professor David James Hamilton. Assistant Pathologist: Dr. George Dean. Dental Surgeon: Dr. W. H. Williamson. Anæsthetist and Medical Electrician: Dr. J. J. Y. Dalgarno. Assistant ditto: Dr. A. Rudolph Galloway. Clinical Registrar: Dr. W. R. Pirie. Joint Treasurers and Secretaries: Mr. W. Carnie and Mr. Charles M. Brown.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ROYAL INFIRMARY, Edinburgh.—Beds are set apart for clinical instruction by the professors of the University of Edinburgh. Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, and on Diseases of the Skin; and in the surgical department on Diseases of the Eye, the Ear, the Larynx, and the Teeth. Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear, and the Skin, and also to cases of Incidental Delirium or Insanity. Three wards are specially set apart for Clinical Instruction to Women Students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists, who also give practical instruction in Pathological Anatomy and Histology. The fees for hospital attendance are as follows—viz.: Perpetual ticket, in one payment, £12; annual ticket, £6 6s.; six months, £4 4s.; three months, £2 2s.; monthly, £1 1s. Separate payments amounting to £12 12s. entitle the student to a perpetual ticket. No fees are paid for any medical or surgical appointment. The appointments are as follows:—1. Resident physicians and surgeons are appointed, and live in the house free of charge. The appointment is for six months, but may be renewed at the end of that period by special recommendation. 2. Special non-resident clerks are appointed for six months. The appointment may be renewed for a like period by special recommendation. 3. Clerks and dressers are appointed by the physicians and surgeons. These appointments are open to all students and junior practitioners holding hospital tickets. 4. Assistants in the Pathological Department are appointed by the pathologists.

ROYAL HOSPITAL FOR SICK CHILDREN, Sciennes-road, Edinburgh.—This hospital, which has been recently built, contains over 100 beds, and is fitted with every modern improvement. A fully equipped out-patient department (medical and surgical) is conducted daily in a building adjoining the hospital. Systematic courses of instruction, which qualify for graduation in the Edinburgh University and elsewhere, are given from time to time throughout the year by the staff. Students may enter at any time. A limited number of Clinical Clerkships are obtainable. Full particulars can be obtained from the Registrar at the hospital.

EDINBURGH EYE, EAR, AND THROAT INFIRMARY, 6, Cambridge-street, Lothian-road.—The Infirmary has been entirely re-arranged and greatly improved by recent structural alterations and the electric light introduced; also the electric power is used for illumination and cauterising purposes in all departments. Clinical Lectures and Instruction are given in this institution, which is open at 1 o'clock daily for out-door patients for Eye Diseases; Mondays, Thursdays, and Saturdays at 12 noon for out-door Ear Patients; and Tuesdays and Fridays at 4 P.M. for out-door Throat Patients. Special Practical Ophthalmoscopic Classes by arrangement. Patients whose diseases require operations or more than ordinary care are accommodated in the house. Consulting Surgeon: Dr. Joseph Bell, F.R.C.S. Surgeons: Dr. J. J. Kirk Duncanson, F.R.C.P.E.; Dr. G. Hunter Mackenzie; Dr. William George Sym, F.R.C.S.E.; Dr. Alexander Black, F.R.C.P.E.; and Dr. Malcolm Farquharson. Dental Surgeon: Mr. G. W. Watson, L.D.S. Treasurer and Secretary: Mr. J. P. Waton, W.S., 13, Hill-street.

GLASGOW HOSPITAL AND DISPENSARY FOR DISEASES OF THE EAR, 28, Elmbank-crescent.—The hospital, which contains twelve beds for in-door patients, is always open for urgent cases. Hours of surgeons' visits, 2 P.M. daily; clinical teaching daily. Out-patients are seen on Mondays, Tuesdays, Wednesdays, Thursdays, Fridays, and Saturdays, at 2 P.M., by Dr. Barr and assistants. Course of Lecutres and Clinical Instruction given during winter months by Dr. Barr.

GLASGOW WESTERN INFIRMARY.—This hospital adjoins the University of Glasgow. Number of beds upwards of 400. Special wards are set apart for Diseases of Women and for Affections of the Skin. In the out-patient department there are special cliniques for Diseases of Women and for Diseases of the Throat, Ear, and Teeth. The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class. All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom. In the Pathological Department the course is both systematic and practical, and extends through the winter and following summer; these are likewise recognised by the University for graduation. Nine resident assistants are appointed annually, without salary, from those who have completed their course. The fee for the hospital practice, including the various courses of clinical instruction, is 20 guineas in one payment, or in two equal instalments for the first and second year; for six months, 7 guineas; and for three months, 4 guineas.

ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow, situated at Garnet Hill.—This hospital was opened in December 1882, and is now available to medical students for clinical instruction in the diseases peculiar to childhood. The hospital includes 80 beds for non-infectious cases only. A specially designed Dispensary, or Out-patient Department, was opened in October, 1888. Students may be enrolled at any time. Fee £1 1s. per annum, admitting to both Hospital and Dispensary. Particulars on applying to the House Surgeon, 45, Scott-street, Garnet-hill, Glasgow.

GLASGOW OPHTHALMIC INSTITUTION, 126, West Regent-street (30 beds).—Clinical and systematic course of lectures for students during the winter and summer sessions. In-patients, 405; out- or dispensary patients, 11,161. Operations on Wednesdays and Saturdays. Consulting Surgeon: D. N. Knox, M.B., C.M., F.F.P.S.G. Acting Surgeon: A. Maitland Ramsey, M.D. Assistant Surgeon: John Rowan, M.B, C.M. House Surgeons: Robert Taylor, M.B., C.M.; J. H. Wolfe, L.F.P.S., &c. This institution has recently been amalgamated with the Glasgow Royal Infirmary, of which it forms an integral part.

Digitized by Google

GLASGOW EYE INFIRMARY, Berkeley-street and Charlotte-street.—This institution, the largest of its kind in Scotland, was founded in 1824. The Infirmary now consists of two large buildings—that in Berkeley-street being occupied as the Infirmary proper, and that in Charlotte-street (new buildings opened June, 1894) as a dispensary. The Infirmary is devoted exclusively to the treatment of Diseases of the Eye, and is intended primarily to provide treatment, and, when necessary, board and lodging, for those who are unable to do so for themselves. The average number of new patients for the last ten years has been 13 053, and the total number of cases treated in 1896 was 20,372. The Medical Staff is as follows:—Senior Surgeon: Thomas Reid, M.D. Surgeons: Thomas S. Meighan, M.D., and A. Freeland Fergus, M.D. Assistant Surgeons: William Robertson, M.D. Andrew Wilson, M.B., C.M., and James Hinshelwood, M.A., M.D. Pathologist: Leslie Buchanan, M.B., C.M. House Surgeon: Francis J. Barker, M.B., C.M. Assistant House Surgeon: Francis R. Hill, M.B., C.M. Clinical Assistants: A. Lewis M'Millan, M.B., C.M.; William Weir, B.Sc., M.B., C.M.; W. Ernest Thomson, M.A., M.D.; Henry L. G. Least, M.D.; W. Cochrane Murray, M.B., C.M.; Thomas D. Moffat, M.B., C.M.; Leslie Buchanan, M.B., C.M.

Regulations as to Attendance of Students.—(1) Gentlemen may attend as students on payment to the treasurer of the following fees:—For six months £1 1*s.*, twelve months £2 2*s.* (2) All students when duly entered in the Infirmary Register may attend the clinical instruction of any or every member of the medical staff on production of their tickets. The days on which the surgeons respectively attend to receive patients may be ascertained at the Infirmary. Students have the privilege of being present in the Dispensaries at such hours as are arranged. They may enter the wards along with the Surgeon whose clinique they are attending when he visits his patients. They may also be present at operations under the sanction of the surgeon operating, but no student may enter the wards or operating-room except under the aforesaid regulation. Students may be allowed the use of the journals and case-books for examination on applying to the House Surgeon. The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine. Secretary: William George Black, 88, West Regent-street.

IRISH SCHOOLS OF MEDICINE.[1]

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Belfast.—Ten Junior Scholarships have been founded in the Faculty of Medicine of the annual value of £20 each. Two are tenable by matriculated students, of the first, second, third, fourth, and fifth years of their course respectively. The examinations for Scholarships take place at the commencement of the session. Class Prizes are awarded at examinations which take place at the close of the session. The Exhibitions, &c., of the Royal University of Ireland are also open to students. Lectures in Medicine at Queen's College, Belfast, will commence on Oct. 19th and end on March 31st. The Summer Session will begin on May 2nd. Clinical instruction is given at the Royal Hospital. The Ulster Hospital for Diseases of Women and Children, the Maternity Hospital, the Ophthalmic Hospital, the Ulster Eye, Ear, and Throat Hospital, the Hospital for Sick Children, and the District Lunatic Asylum are open to students. A pamphlet containing full information can be had free on application to the Registrar, Queen's College, Belfast.

QUEEN'S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well-ventilated dissecting-room, with physiological, toxicological, and pathological laboratories, materia medica, anatomical and pathological museums, as well as a room for surgical and obstetrical instruments and appliances. There are well-appointed physical and chemical laboratories, and a large natural history museum in the adjoining building, and part of the College ground is laid out as a botanical garden. The plant houses are well filled with plants, and are open to the students in the class of Botany.

Fees.—For Practical Anatomy and for Practical Chemistry, £3 each course; for Anatomy and Physiology, £3 first course, and £2 for each subsequent course. Other medical classes, £2 first course, and £1 each subsequent course. Eight scholarships (value about £30 each), as well as several exhibitions and class prizes, are awarded every year.

QUEEN'S COLLEGE, Galway.—No particulars received.

[1] For Scholarships see page 502 et seq.

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION.

ADELAIDE MEDICAL AND SURGICAL HOSPITALS, Peter-street, Dublin.—Fee for nine months' hospital attendance, £12 12*s.*; six months, £8 8*s.* Summer, three months, £5 5*s.*

Staff.—Physicians: James Little, M.D., M.R.I.A.; Wallace Beatty, M.D., F.R.C.P.I.; H. T Bewley, M.D., F.R.C.P.I. Surgeons: F. T. Heuston, M.D., F.R.C.S.I.; J. H. Scott, M.B., F.R.C.S.I.; T. E. Gordon, M.B., F.R.C.S.I. Obstetric Surgeon: W. J. Smyly, M.D., F.R.C.P.I. Ophthalmic Surgeon: H. R. Swanzy, M.B., F.R.C.S.I. Pathologist and Bacteriologist: J. Alfred Scott, M.D., F.R.C.S.I. Medical and Surgical Registrar: G. Peacocke, M.B., B.Ch. House Surgeon: S. Horace Law, M.B., B.Ch.

A resident surgeon is elected yearly, and three resident pupils half-yearly. At the termination of the session prizes in Clinical Medicine and Surgery and in Obstetric Medicine will be awarded.

Hudson Scholarship.—In addition to the junior prizes, the Hudson Scholarship, £30 and a gold medal, as well as a prize of £10, together with a silver medal, will be awarded at the end of the session for proficiency in Clinical Medicine and Medical Pathology, Clinical Surgery and Surgical Pathology, Pathological Histology, Surgical Appliances, including instruments and bandaging, Ophthalmology and Gynæcology.

The certificates of attendance are recognised by all the Universities and licensing bodies in the United Kingdom. Further particulars may be obtained from Mr. F. T. Heuston.

COOMBE LYING-IN HOSPITAL AND GUINNESS DISPENSARY FOR THE TREATMENT OF DISEASES PECULIAR TO WOMEN, Dublin.—This hospital contains nearly 70 beds, and consists of two divisions, one of which is devoted to lying-in cases, and the other to the treatment of the diseases peculiar to women. The maternity department is one of the largest in Ireland, 3000 cases being annually treated either as intern or extern patients. A regular course of lectures is delivered in the hospital, and clinical instruction is given daily at the bedside. There are two large dispensaries connected with the institution, at one of which instruction is given on the General Diseases of Women and Children, and in the other on the Diseases Peculiar to Women. There is accommodation for a limited number of intern pupils, who enjoy exceptional advantages of acquiring a practical knowledge of this branch of their profession. Two Resident Pupil Midwifery Assistants and one Clinical Clerk are elected half-yearly from among the pupils of the hospital. Certificates of attendance at this hospital are accepted by all licensing bodies, and the diploma is recognised by the Local Government Board as a full legal midwifery qualification. Fees (six months' course): extern pupils, 8 guineas, half payable in advance; intern pupils, 18 guineas for six months' residence. If pupils enter as interns by the month the fees are £4 4*s.* for first month, and £3 3*s.* for each succeeding month. Intern pupils enjoy very special advantages, which can be learned on application. Registration fee on entrance, 10*s.* 6*d.* Students can enter for attendance at any time. Further particulars may be had on application to the Master or the Registrar at the hospital.

SIR PATRICK DUN'S HOSPITAL.—Fees for attendance of students—nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* The hospital is open to extern students as well as to the students of Trinity College, and the certificates are recognised by all the licensing bodies in the kingdom. Dr. Taylor, Secretary to the Medical Board, will give any further information. The Winter Session begins on Oct. 1st.

MEATH HOSPITAL AND COUNTY DUBLIN INFIRMARY.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers has recently been added. The certificates of this hospital are recognised by all the universities and licensing bodies of the United Kingdom.

Medical and Surgical Resident Pupils and Clinical Clerks and Dressers are appointed every six months, and a House Surgeon is elected annually. A prospectus giving the complete arrangements for the Medical and Surgical classes for the coming session may be obtained from the Secretary of the Medical Board, R. Glasgow Patteson, F.R.C.S, 20, Lower Baggot-street, Dublin.

MATER MISERICORDIÆ HOSPITAL, Dublin. — Consulting Physician: Sir Francis R. Cruise. Physicians: Sir Christopher Nixon, Drs. Joseph Redmond, Michael Boyd, and John Murphy. Assistant Physician: Dr. Martin Dempsey. Medical Registrar: Dr. John O'Donnell. Surgeons: Messrs. Patrick Hayes, Charles Coppinger, Arthur Chance, and John Lentaigne. Assistant Surgeon: Mr. Hugh Blaney. Obstetric Physician: Dr. Thos. More Madden. Ophthalmic Surgeon: Mr. Louis Werner. Dental Surgeon: Mr. Daniel Corbett, jun. Pathologist: Dr. Edmond McWeeney. Anæsthetist and Surgical Registrar: Dr. Michael O'Sullivan. House Physician: Dr. Whelan. House Surgeons: Messrs. Mitchell, Birmingham, Hamilton, and Kerr. This hospital, the largest in Dublin, at present containing 323 beds, is open at all hours for the reception of accidents and urgent cases. Fifty beds are specially reserved for the reception of patients suffering from fever and other contagious diseases. Instruction at the bedside will be given by the Physicians and Surgeons at 9 A.M. daily. Clinical Instruction will commence on Monday, Oct. 4th, at 9 A.M. A course of Clinical Instruction on Fever will be given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies, may be obtained. Opportunities are afforded for the study of Diseases of Women in the ward under the care of the Obstetric Physician, and at the Dispensary held on Tuesdays and Saturdays. Ophthalmic Surgery will be taught in the Special Wards and Dispensary. Surgical Operations will be performed on Mondays, Tuesdays, Fridays, and Saturdays at 10 o'clock. Connected with the hospital are extensive Dispensaries, which afford valuable opportunities for the study of general Medical and Surgical Diseases, Accidents, &c. Instruction will be given on Pathology and Bacteriology. Junior Appointments: A House Physician and four House Surgeons will be appointed annually. Eight resident pupils will be elected from the most attentive of the class to hold office for six months. For the current session the elections will take place in the first week of November and in the first week of May. Dressers and Clinical Clerks will be appointed, and certificates will be given to those who perform their duties to the satisfaction of the staff. Leonard Prizes: One Gold and one Silver Medal will be offered for competition annually in the subject of Medicine, and one Gold and one Silver Medal in the subject of Surgery. Junior Leonard Prizes: One prize value £3 and one prize value £2 will be awarded in Medicine, and one prize value £3 and one prize value £2 will be awarded in Surgery. They will be awarded on the aggregate of marks gained for Reports of Cases and at a Clinical Examination to be held at the close of the summer session. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the Universities and licensing bodies in the United Kingdom. Private Wards have been opened for the reception of Medical and Surgical cases. A Training School and Home for Trained Nurses have been opened in connexion with the Hospital.

Terms of attendance.—Nine months, £12 12*s.*; six winter months, £8 8*s.*; three summer months, £5 5*s.* Entries can be made with any of the physicians or surgeons, or with the Registrar, Arthur Chance, F.R.C.S., 90, Merrion-square. A prospectus containing in detail the arrangements for Clinical Instruction, Prizes, &c., may be obtained from the Secretary, Dr. Joseph Redmond, 8, Clare-street, Dublin.

RICHMOND, WHITWORTH, AND HARDWICKE HOSPITALS, North Brunswick-street, Dublin.—These hospitals contain 312 beds—110 for Surgical cases, 82 for Medical cases, and 120 for Fever and other epidemic Diseases. A Resident Physician and a Resident Surgeon are appointed each year, and are paid for their services. Clinical Clerks: Five Resident Clinical Clerks are appointed each half-year, and provided with furnished apartments, fuel, &c. These appointments are open not only to advanced Students as formerly, but also to those who are qualified in Medicine or Surgery. The Dressers are selected from among the best qualified of the pupils without the payment of any additional fee. For prospectuses apply to Sir W. Thomson, F.R.C.S., Treasurer, 54, Stephen's-green East; or to T. O'Carroll, M.D., Hon. Sec., 27, Westland-row, Dublin.

ROTUNDA HOSPITAL, Rutland-square, Dublin.—This institution consists of two distinct hospitals—namely, the Lying-in Hospital and the Auxiliary Hospital, the latter for the reception of patients suffering from Uterine and Ovarian Diseases. There is also a large extern maternity and a Dispensary for Diseases Peculiar to Women, which is open daily. Clinical instruction is given daily (Saturdays excepted) in Midwifery and the Diseases peculiar to Women, special attention being directed to the application of antiseptics in Midwifery. Accommodation is provided for a limited number of intern pupils.

DR. STEEVENS'S HOSPITAL.—This hospital, containing beds for 200 patients, is situated close to the Kingsbridge Terminus of the Great Southern and Western Railway, occupying a position in the centre of one of the busiest manufacturing districts of the city, otherwise unprovided with medical institutions, and affords exceptional advantages for clinical instruction. Immediately adjoining is St. Patrick's (Swift's) Asylum for the Insane. The hospital is easily accessible by two lines of tramways. There is a ward entirely devoted to Venereal Disease, a detached building for Fever Cases, and an extensive Out-patient Department, with separate Clinics for Diseases of the Skin, Throat, Eye, Ear, and Teeth.

The hospital is visited daily at 9 A.M. by the physicians and surgeons. The wards are also visited by the resident surgeon each evening. Clinical Lectures are given by the physicians and surgeons during the session. There is accommodation in the hospital for two medical and six surgical resident clinical assistants.

Fees.—Hospital Practice: Nine months, £12 12*s.*; six months, £8 8*s.*; three months, £5 5*s.* Dressership: £10 10*s.* each three months. Further information may be obtained from the Resident Surgeon or from R. A. Hayes, M.D., Hon. Sec., 82, Merrion-square South.

POST-GRADUATE COURSES.

THE LONDON POST-GRADUATE COURSE.—This course is specially arranged to meet the wants of the practitioner and to enable him during his leisure time to brush up his knowledge on subjects about which he may desire further information. It has been both popular and successful and has been attended by men from all parts of the Empire, from all branches of the Services, from the United States of America, as well as from foreign countries. Members can enter for each or all of the courses of lectures for the term, for half the term, or for all the lectures for one week, and thus each can obtain just what he wants and in the shortest possible time. The Vacation Courses have been attended by large numbers of practitioners and have been much appreciated. By this means men who wished to bring themselves abreast of the scientific knowledge of the day have been able to learn the elements of the technique of bacteriology and the latest advances in hygiene in a fortnight's daily course. The staffs of the following hospitals have associated themselves for teaching purposes—viz., the Hospital for Diseases of the Skin, Blackfriars; the London Throat Hospital; and the Bethlem Royal Hospital for Lunatics; and courses are given at the Bacteriological Laboratory, King's College, at the Parkes Museum on Hygiene, at the Cleveland-street Sick Asylum on Clinical Medicine and Surgery, and at the Institute of Preventive Medicine in Clinical Chemistry. The fees are £1 1*s.*, £2 2*s.*, and £3 3*s.*, according to the number of lectures in the course. Further information can be obtained from, and fees should be paid to, Dr. Fletcher Little, Secretary, 32, Harley-street, Cavendish-square, W.

CHARING-CROSS HOSPITAL.—Special series of clinical lectures and practical demonstrations, exclusively arranged for the convenience of practitioners and post-graduate students, are given at the hospital by members of the staff throughout the year. The lectures for the year are arranged in three courses, each course consisting of ten meetings and lasting ten weeks. Two of these courses are held during the winter and one during the summer. The class meets on each Thursday afternoon at 4 P.M. in the board-room of the hospital, and proceeds thence to the wards or other department in which the demonstration may be held. Practitioners wishing to join the class can receive any further information as to the dates and subjects by communicating with the Honorary Secretary or the Honorary Treasurer at the hospital.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY.

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
LONDON UNIVERSITY ..	No. 1.	£40 per annum.	2 years.	By first place with distinction in ANATOMY at July Intermediate M.B. Examination.	M.B. taken within 3 years.
	No. 2.	£40 per annum.	2 years.	By first place, with distinction in PHYSIOLOGY AND HISTOLOGY at July Intermediate M.B. Examination.	Ditto.
	No. 3.	£30 per annum.	2 years.	By first place with distinction in ORGANIC CHEMISTRY at July Intermediate M.B. Examination.	Ditto.
	No. 4.	£30 per annum.	2 years.	By first place with distinction in MATERIA MEDICA and PHARMACEUTICAL CHEMISTRY at July Intermediate M.B. Examination.	Ditto.
	University Scholarship in Medicine.	£50 per annum.	2 years.	By first place with distinction in MEDICINE at M.B. Honours Examination.	
	University Scholarship in Obstetric Medicine.	£30 per annum.	2 years.	By first place with distinction in OBSTETRIC MEDICINE at M.B. Honours Examination.	
	University Scholarship in Forensic Medicine.	£30 per annum.	2 years.	By first place with distinction in FORENSIC MEDICINE at M.B. Honours Examination.	
	University Scholarship in Surgery.	£50 per annum.	2 years.	By first place with distinction in B.S. Honours Examination.	
ST. BARTHOLOMEW'S MEDICAL SCHOOL	Entrance Scholarships. No. 1.	£75.	....	Open Competitive Examination in PHYSICS and CHEMISTRY.	Full Course at St. Bartholomew's Hospital.
	,, No. 2.	£75.	....	Open Competitive Examination in BIOLOGY and PHYSIOLOGY.	Ditto.
	,, No. 3.	£150.	....	Open Competitive Examination in PHYSICS, CHEMISTRY, and BIOLOGY.	Ditto.
	Preliminary Scientific Exhibition.	£50.	....	Open Competitive Examination in PHYSICS, CHEMISTRY, and BIOLOGY.	Ditto.
	Jeaffreson Exhibition.	£20.	....	Open Competitive Examination in LATIN, MATHEMATICS, and GREEK, FRENCH, or GERMAN.	None.
	Shuter Scholarship.	£50.	....	Competitive Examination among Cambridge Graduates in ANATOMY, PHYSIOLOGY, and MATERIA MEDICA.	None.
	Junior Scholarships.				
	,, No. 1.	£30.	....	Competitive Examination among Students in ANATOMY and BIOLOGY.	None.
	,, No. 2.	£20.	....	Ditto.	None.
	,, No. 3.	£25.	....	Competitive Examination in CHEMISTRY, PHYSICS, and HISTOLOGY.	None.
	,, No. 4.	£15.	....	Ditto.	None.
	Senior Scholarship.	£50.	....	Competitive Examination among Students in ANATOMY, PHYSIOLOGY, and CHEMISTRY.	Study at St. Bartholomew's Hospital.
	Kirkes Scholarship.	£30 and Medal.	....	Competitive Examination among Students in CLINICAL MEDICINE.	
	Brackenbury Scholarships.				
	,, No. 1.	£39.	....	Competitive Examination among Students in MEDICINE.	
	,, No. 2.	£39.	....	Competitive Examination among Students in SURGERY.	
	Lawrence Scholarship.	£42 and Medal.	....	Competitive Examination among Students in SURGERY, MEDICINE, and MIDWIFERY.	None.
	Sir Geo. Burrows Prize.	£10 10s.	....	Competitive Examination in PATHOLOGY among Students.	
	Skynner Prize.	£15.	....	Competitive Examination in REGIONAL and MORBID ANATOMY among Students.	
	Matthews Duncan Medal and Prize.	£20.	....	Competitive Examination among Students in MIDWIFERY and GYNÆCOLOGY.	None.
	Research Studentship in Pathology.	£100.	....	By Election, on the recommendation of the School Committee.	None.
CHARING CROSS HOSPITAL AND COLLEGE	Entrance Scholarships, open to students at the commencement of curriculum.				
	Livingstone.	100 guineas.	....	The Livingstone and Huxley Scholarships are awarded annually at the commencement of each Winter Session, after a competitive examination in the following groups of subjects: — (1) ENGLISH, including LANGUAGE, HISTORY, and GEOGRAPHY; (2) Any two of the following four languages —LATIN, GREEK, FRENCH, and GERMAN; (3) MATHEMATICS,	Open to all general students.
	...	60 ,,	....		Open to all general students.

	Natural Science	£60.	....	Competitive Examination in subjects of Preliminary Scientific of London University.	For Students entering in the Summer Session.
	Arts Scholarship (Entrance).	£50.	....	Competitive Examination as for the Guthrie Scholarship, except that the Latin Book is that of the London Matriculation of the preceding January.	Ditto.
	Ditto.	£50.	....	Ditto.	Ditto.
	Treasurer's Prize.	£10 10s.	....	Competitive Examination among First-year Students in ANATOMY, PHYSIOLOGY or BIOLOGY, and CHEMISTRY.	
	President's Prize.	£21.	....	Competitive Examination among Second-year Students in ANATOMY, PHYSIOLOGY, and HISTOLOGY.	
	Sturges Prize in Clinical Medicine.	£10.	....	Notes and commentaries on 6 cases.	
	Clinical Surgery.	£5.	....	Ditto on 12 cases.	
	Chadwick Prize.	£21 in books or instruments.	....	Competitive Examination among Medical Students in MEDICINE and SURGERY, including PATHOLOGY and APPLIED ANATOMY and PHYSIOLOGY.	
	Bird Medal and Prize.	£14 in medal, books, or instruments.	....	Competitive Examination in MIDWIFERY and DISEASES of WOMEN, MEDICINE, and PATHOLOGY among Students who have completed their Fourth Winter Session at the Westminster Hospital School of Medicine.	
	Fish Prize.	£20.	....	PATHOLOGY by paper, also *vivâ voce* in Post-mortem Room and on MICROSCOPIC and MUSEUM PATHOLOGY.	
LONDON SCHOOL OF MEDICINE FOR WOMEN	Entrance Scholarship.	£30.	....	Competitive Examination in ENGLISH, LATIN, ARITHMETIC, EUCLID, and ALGEBRA.	
	Stuart Mill Scholarship.	£30.	4 years.	Ditto.	Candidates must be willing to enter into a legal arrangement to practise in India under the Countess of Dufferin's Fund.
	Fanny Butler Scholarship.	£14 10s.	4 years.	Ditto.	Candidates must be willing to work in connexion with the Church of England Zenana Missionary Society.
	John Byron Bursary.	£20.	2 to 4 years.	....	Offered to students already in the school requiring assistance for the prosecution of their medical studies.
	Two Mackay Prizes.	£20 each.	....	Given to the two Students gaining the highest number of marks in the School Examinations during the first two years of Medical Study.	
	Helen Prideaux Scholarship.	£50.	....	Given to Graduates of not more than 3 years' standing for Original Work.	
OXFORD UNIVERSITY ..	Burdett-Coutts Scholarships.	£80 per annum.	2 years.	Competitive Examination.	....
	Radcliffe Trav. Fellowship.	£200 ,, ,,	3 years.	Ditto.	Foreign Travel for purpose of Medical Study.
	Rolleston Prize.	£60 ,, ,,	....	Original Research.	

* The Latin Book is that of the Matriculation, University of London, in the preceding June.

SCHOLARSHIPS GIVEN IN AID OF MEDICAL STUDY—*continued*.

INSTITUTION.	TITLE OF SCHOLARSHIP, &c.	ANNUAL OR TOTAL VALUE.	HOW LONG TENABLE.	HOW OBTAINABLE.	CONDITIONS ATTACHED TO TENURE.
UNIVERSITY OF DURHAM	Four Scholarships.	£25 a year each.	4 years.	Examination in GOSPEL OF ST. LUKE in GREEK, LATIN, ARITHMETIC, ALGEBRA, EUCLID, and ENGLISH HISTORY.	Students pursuing their medical studies and not of a sufficient standing to proceed to a Degree in Medicine.
College of Medicine	Dickinson Scholarship.	Interest on £400 and Gold Medal.	....	Examination in MEDICINE, SURGERY, MIDWIFERY, and PATHOLOGY.	Full students of the College of Medicine who have passed the intermediate examination of any of the Licensing Bodies named in Schedule A of the Medical Act, 1858.
	Tulloch Scholarship.	Interest on £400	....	Examination in ANATOMY, PHYSIOLOGY, and CHEMISTRY.	No student is eligible who commenced his medical curriculum more than two academical years before the date of examination.
	Charlton Memorial Scholarship.	Interest on £700	....	....	Open to full students of the College entered for the class on the Principles and Practice of Medicine.
	Gibb Scholarship.	Interest on £500	....	Awarded annually as a Scholarship in PATHOLOGY to full student who passes the best examination in that subject.	No student eligible after completion of his curriculum.
	Luke Armstrong Memorial Scholarship.	Interest on £680	....	Original Essay on some subject in COMPARATIVE PATHOLOGY.	Open to all graduates in Medicine or Hygiene and candidates for these degrees who have spent six months at the University, and whose age does not exceed thirty years.
	Stephen Scott Scholarship.	Interest on £1000.	....	Original essay on any Surgical subject.	Any graduate in Medicine or Surgery of the University or any student of the College of Medicine. Student's age must not exceed 30 years.
	Heath Scholarship.	Interest on £4000.	....	Original essay on CONGENITAL DEFORMITIES: THEIR PATHOLOGY AND TREATMENT.	All graduates in Medicine or Surgery of the University are eligible.
Royal Infirmary...	Goyder Memorial Scholarship.	Interest on £325.	Annually.	Student who most distinguishes himself in CLINICAL MEDICINE AND CLINICAL SURGERY at the Royal Infirmary.	
MASON COLLEGE, BIRMINGHAM	Ingleby Scholarships (1 or more).	£10 to £15.	1 year.	....	Candidates must have spent first two years of curriculum at the College.
	Sydenham Scholarship.	£10 10s. per annum.	3 years.	Award of Council to orphan sons of Medical Practitioners.	
	Sands Cox Scholarship.	£10 10s. per annum.	3 years.	Competitive Examination among sons of Medical Practitioners under eighteen years of age in ARTS SUBJECTS.	
	Queen's Scholarship.	£10 10s. per annum.	3 years.	Open Competitive Examination in ELEMENTARY SCIENCE, with a Modern Language.	
	Dental Scholarship.	£7 17s. 6d.	2 years.	Open Competitive Examination in subjects learned during apprenticeship.	
VICTORIA UNIVERSITY ...	Gilchrist Scholarship.	£50.	3 years.	Awarded annually to the candidate who shall stand highest at the June preliminary examination of the Victoria University provided that he pass in the first division.	Candidates must be over 18 years of age on July 1st in the year of competition.
	University Scholarship in Medicine.	£50.	1 year.	Awarded annually on the results of the second examination for the degrees of M.B. and Ch.B.	
OWENS COLLEGE, MANCHESTER	General Entrance Scholarships.	....	....	....	Open to candidates above 16 and under 20 years of age.
	Rogers.	£40.	2 years.	Subjects: GREEK, LATIN TRANSLATIONS AT SIGHT, and PROSE COMPOSITION.

NOTE.—*Glasgow University.*—In addition to the bursaries mentioned above in connexion with Queen Margaret College, there will be at least eleven bursaries and prizes of the aggregate value of about £218 awarded during the session 1897-98.

PUBLIC HEALTH.

INSTRUCTION FOR DIPLOMAS IN STATE MEDICINE.

ENGLAND.

THE following recommendations, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," were adopted by the General Medical Council in 1896.[1] The regulations require that—"(1) A period of not less than twelve months shall elapse between the attainment of a first registrable qualification in Medicine, Surgery, and Midwifery and the examination for a diploma in Sanitary Science, Public Health, or State Medicine; (2) every candidate shall have produced evidence of having attended, after obtaining a registrable qualification, during a period of six months, practical instruction in a laboratory approved of by the body granting the qualification; (3) every candidate shall have produced evidence of having for six months practically studied the duties of out-door sanitary work either under a medical officer of health who is a teacher in public health in a recognised school, or under the medical officer of health of a county or of a single sanitary district of 50,000, or a combination of districts of 35,000 inhabitants in England, or of 30,000 in Scotland or Ireland; (4) the examination shall have been conducted by examiners specially qualified, and shall comprise laboratory work as well as written and oral examination; (5) the rules as to study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan. 1st, 1890." It was enacted by Section 18 (2) of the Local Government Act, 1888 [England and Wales], that after Jan. 1st, 1892, no such appointment (that of medical officer of health) may be made in any county, or in any district or combination of districts with a population of 50,000 or upwards, unless the officer—having, of course, qualifications in Medicine, Surgery, and Midwifery—is registered as the holder of a diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act, 1886, or has during any three consecutive years preceding 1892 been medical officer of a district or combination of districts with a population of 20,000 at least, or has for three years previously to Aug. 13th, 1888, been a medical officer or inspector of the Local Government Board. With the sanction of the Local Government Board, the same person may be appointed medical officer for two or more districts.

London University.—Sanitary Science is included under the head of State Medicine in the M.D. degree, and a certificate has to be produced showing that a course of practical instruction has been attended for the prescribed period, and that the course has included such chemical, microscopical, and meteorological work and exercises as more especially relate to sanitation. The attendance includes six months' practical instruction in a laboratory and six months' out-door sanitary work. Certificates will be received from the holder of any public health office directly or indirectly subject to control by a Secretary of State or

[1] The regulations were last settled on June 9th, 1896, and came into operation on Jan. 1st, 1897.

a Government Department. If a candidate have studied State Medicine for one year and have held for a period of two years the position of medical officer of health in any sanitary district, or without having studied State Medicine have held for a period of three years the position of medical officer of health in any sanitary district, he will be eligible for the examination.

Cambridge University.—Examinations in so much of State Medicine as is comprised in the functions of medical officers of health will be held in Cambridge, beginning on the first Tuesday in April and in October, and ending in the following week. Any person whose name is on the Medical Register is eligible as a candidate for this examination: Provided (*a*) he be in his twenty-fourth year at least when he presents himself for the first part of the examination, and have attained twenty-four years of age before he presents himself for the second part; (*b*) a period of not less than twelve months shall have elapsed between the time when he first obtained a registrable qualification and the time when he presents himself for either part of the examination; (*c*) he produce evidence of having, before or after obtaining a registrable qualification, attended the clinical practice of a hospital for infectious diseases approved by one of the licensing bodies recognised under the Medical Acts; (*d*) he produce evidence of having, after obtaining a registrable qualification, attended during a period of six months on one or more courses, approved by the Syndicate, of practical laboratory instruction in Chemistry, Bacteriology, and the Pathology of those diseases of animals that are transmissible to man; (*e*) he produce evidence of having, after obtaining a registrable qualification, practically studied for six months the duties of out-door sanitary work under the medical officer of health of a county or large urban district, unless he have himself held an appointment as medical officer of health under conditions not requiring a special sanitary diploma. The provisions (*b*), (*c*), (*d*), (*e*) are not to apply to (*a*) candidates whose names shall have been placed on the Medical Register on or before Jan. 1st, 1890, or who have obtained a registrable qualification on or before that date; (*β*) candidates who have for a period of three years held the position of medical officer of health to any county, or to any urban district of more than 20,000 inhabitants, or to any entire rural sanitary district. The examination is in two parts. The first part will comprise Physics and Chemistry; the principles of chemistry and methods of analysis, with especial reference to analyses of air, water, and food; application of the microscope, including the investigation of micro-organisms; the laws of heat and the principles of pneumatics, hydrostatics, and hydraulics, with especial reference to ventilation, water-supply, drainage, construction of dwellings, disposal of sewage and refuse, and sanitary engineering in general; meteorology in relation to health; sources of water-supply; and statistical methods in their application to public health. The second part will comprise Laws and Statutes relating to public health; origin, propagation, pathology, and prevention of epidemic and infectious diseases, including those diseases of animals that are transmissible to man; effects of overcrowding, vitiated air, impure water, and bad or insufficient food; unhealthy occupations and the diseases to which they give rise; water-supply and drainage in reference to health; nuisances injurious to health; distribution of diseases within the United Kingdom, and effects of soil, season, and climate. The following is a list of Colleges and Schools of Medicine at which the courses of laboratory instruction have, for the purposes of this examination, been already approved by the Syndicate: The Chemical and Pathological Laboratories, Cambridge; the University of Edinburgh; the London Hospital Medical College; St. Bartholomew's Hospital Medical College; King's College, London; University College, London; the Army Medical School, Netley; Owens College, Manchester; the University of Durham Medical School, Newcastle-on-Tyne; Mason College, Birmingham; University College, and Southern Hospital School, Liverpool; St. Mary's Hospital Medical College; Charing-cross Hospital College; University College, Bristol; and Yorkshire College, Leeds. The examination in both parts will be oral and practical, as well as in writing. One day at least will be devoted to practical laboratory work, and one day to oral and practical examination in, and reporting on, subjects connected with out-door sanitary work. No candidate will be approved by the examiners who does not show a high proficiency in all the branches of study, scientific and practical, which concern the public health. Every candidate will be required to pay a fee of £5 5*s.* before admission or readmission to *either part* of the examination. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a diploma testifying to his competent knowledge of what is required for the duties of a medical officer of health. All applications for information respecting this examination should be addressed to Dr. Anningson, Barton-road, Cambridge, Secretary to the Syndicate. Candidates who desire to present themselves for the examination in October next must send in their applications on forms supplied for the purpose and transmit the fees to J. W. Clark, M.A., Registrary, University of Cambridge, on or before Sept. 17th. Cheques should be crossed "Barclay and Co., Ltd." The fee for either part of the examination cannot be returned to any candidate who fails to present himself; but he will be entitled, without an additional fee, to be a candidate on one subsequent occasion. The applications of candidates whose names have not been on the Medical Register for three years should be accompanied by a certificate of birth or other proof of age.

University of Oxford (*Diploma in Public Health*).—An examination, open to all registered Medical Practitioners, conducted partly in writing, partly *viva voce*, and in each subject partly practical, is held in Michaelmas Term in the following subjects:—General Pathology, with special relation to Infectious Diseases, the Laws relating to Public Health, Sanitary Engineering, Vital Statistics. The fee for admission to the examination is £10. Candidates (*a*) must have spent after registration a period of at least six months studying in a public health laboratory approved by the Board of the Faculty of Medicine. Candidates must also (*b*) have had their names on the Medical Register of the United Kingdom for a period of at least twelve months; (*c*) have spent after registration a period of study, of not less than six months in all, under the medical officer of health of a county or of a city or town containing at least 50,000 inhabitants, or under two or more such medical officers of health. Certificates of proficiency are granted to those who pass this examination.

University of Durham.—Sanitary Science is the special object of the degrees in Hygiene. Candidates for the degree of Bachelor in Hygiene (B.Hy.) must be at least twenty-two years of age and registered, and before presenting themselves for examination must have been for at least twelve months graduates in Medicine of a recognised university. They shall spend six months at Newcastle-upon-Tyne studying Public Health, Comparative Pathology, Practical Bacteriology, Outdoor Sanitary Work, Infectious Diseases, Sanitary and Practical Chemistry. They have to pass an examination in Sanitary Chemistry, Physics, Sanitary Legislation, Comparative Pathology, Vital Statistics, Nosology, Distribution of Health and Disease, Sanitary Medicine, and Practical Hygiene. The fee for the examination for the degree of B.Hy. is 10 guineas, and for the degree £6. Candidates for the degree of Doctor in Hygiene (D.Hy.) must have acquired the degree of Bachelor in Hygiene, must for two years subsequently have been engaged in practice as a Medical Officer of Health, and must write an essay upon some practical hygienic subject. The fee for the examination for the degree of D.Hy. is £5, and for the degree £6. The regulations for education and examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised university, and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination and diploma in Public Health is ten guineas.

Victoria University.—An examination in Public Health is held yearly under the following regulations: The examination is in two parts, and is written, oral, and practical. Candidates before entering for either part of the examination must have held for not less than twelve months a registrable qualification in Medicine, Surgery, and Midwifery, and must present satisfactory certificates of having attended courses of instruction in Public Health and in Chemistry as applied to Public Health in a college of the University, or in a college or medical school recognised for this purpose by the University; of having attended, after obtaining a registrable qualification, during at least six months, practical instruction in a laboratory approved by the University, the courses including Chemistry as applied to Public Health, Bacteriology, and the Pathology of those diseases of animals which

Digitized by Google

are communicable from animals to man; of having attended for three months the clinical practice of a hospital for infectious diseases; of having practically studied the duties of out-door sanitary work for not less than six months under the Medical Officer of Health of a county or of a large urban district. Candidates may present themselves for Parts I. and II. separately or at the same time, provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £5 5s., and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £3 3s. Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin on the third Monday in July each year.

Royal College of Physicians of London and the Royal College of Surgeons of England.—The following are the regulations for obtaining the diploma in Public Health: Section 1: Candidates must be registered under the Medical Act. The examination consists of two parts. The fee for each part is £5 5s. A candidate intending to present himself must give fourteen days' written notice to the Secretary, at the Examination Hall, Thames Embankment, W.C. A candidate registered under the Medical Act on or before Jan. 1st, 1890, will be admissible to Part I. of the examination on producing evidence of being at least twenty-three years of age, and to Part II. on producing evidence of being at least twenty-four years of age. A candidate registered under the Medical Act after Jan. 1st, 1890, will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification in Medicine, Surgery, and Midwifery for at least twelve months; (2) of having attended, after obtaining such registrable qualification, practical instruction in a laboratory recognised by the Examining Board in England during a period of six months; and (3) of being at least twenty-three years of age. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having, during a period of six months after obtaining a registrable qualification, either practically studied the duties of out-door Sanitary Work under the medical officer of health of a county or large urban district or else held appointment as medical officer of health under conditions not requiring the possession of a special Sanitary diploma; (2) of having attended the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England, either before or after obtaining his registrable qualification in Medicine, Surgery, and Midwifery (this certificate is not required in the case of a candidate who produces evidence that he has commenced special study of Sanitary Science before Jan 1st, 1894); and (3) of being at least twenty-four years of age.

King's College, London.—The necessary Laboratory Instruction to comply with the regulations of the various Universities and other Medical Licensing Bodies will be given by Professor William R. Smith, M.D., D.Sc., and Professor Edgar M. Crookshank, M.B. Lond. The syllabus includes Physics, Chemistry, Microscopy; Parasites and other Organisms Infesting Food-stuff or the Human Body; Bacteriology, including the Cultivation and Recognition of Micro-organisms. The course will last six months, four months of which will be spent in the Laboratories of Public Health, and two months in the Bacteriological Laboratory. Fee 20 guineas, payable in advance in the College Office. Under the direction of Professor William R. Smith, M.D., D.Sc., and Demonstrator C. G. Moor, M.A., practical instruction will be given in the laboratories in the methods of Analysis of Air, Water, Foods, &c.; Detection of Poisons. Fees, one month, £4 4s.; three months, £10 10s. The laboratories are also available for original investigations and practical work in Public Health, and are open daily from 9 A.M. to 4 P.M. and on Saturdays to 1 P.M. In Public Health special classes will be held during the winter session by Professor W. R. Smith; fee, £12 12s. The Bacteriological Laboratory is open daily for original research under the direction of the professor and demonstrator of Comparative Pathology and Bacteriology. For one month for original research, 3 guineas. For a longer period by arrangement. For one month for private study, with supervision, 4 guineas. For a longer period by arrangement. Practical course for a month, with attendance on lectures, 5 guineas. For a year, 30 guineas. Professor H. G. Seeley, F.R.S., will deliver a course of six lectures on Physiography. For further particulars connected with any of the foregoing classes apply to Professor W. R. Smith, King's College, London.

University College, Bristol.—A course of lectures on the Principles and Practice of Hygiene is given at the College by D. S. Davies, M.D. Lond., D.P.H. Cantab., on Mondays and Fridays, 10–11 A.M., commencing on the first Monday in October. A six months' course of Practical Laboratory Instruction is given at the Western Counties' Laboratory, Park-street, by Mr. F. Wallis Stoddart, commencing on the first Wednesday in October, and including the subjects of Chemistry, Physics, Bacteriology, and Parasites. Demonstrations on the provisions and practical working of the various Acts relating to Public Health and on the Orders, Circulars, and By-laws of the Local Government Board are delivered by Mr. J. C. Heaven on Mondays and Fridays, commencing on the first Monday in October. Gentlemen taking out the course are admitted to practical out-door sanitary work during the session, under the supervision of the Medical Officer of Health for the city and port of Bristol. They are considered as pupil assistants, and are required to carry out diligently such of the duties of medical officers of health as they may be directed to undertake. Facilities are afforded during the course for the study of those diseases of the lower animals which are communicable to man. Fee for the entire course, 20 guineas.

SCOTLAND.

Edinburgh University.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh—viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least twenty hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended lectures on Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than eighteen months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom, or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of forty lectures at least; one of these courses shall deal with medicine and the other with engineering, each in its relation to public health. They must also give evidence (1) that for six months they have practically studied sanitary work under the medical officer of health of a county or borough or district containing a population of not less than 25 000; (2) that they have had three months' clinical instruction regarding fevers and infectious diseases; and (3) that they have had three months' instruction in mensuration and drawing. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £3 3s. for the First and £3 3s. for the Second B.Sc. Examinations, and £10 10s. for the degree of D.Sc.

University of Aberdeen.—The Diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom; and a period of not less than twelve months must elapse between medical graduation and entrance to the examination for the diploma. Every candidate must produce evidence of having attended, after graduation in Medicine, during a period of six months, practical instruction in Hygiene in a laboratory approved of by the University, together with having for a like period after graduation practically and daily studied the duties of out-door sanitary work under the Medical Officer of Health

Digitized by Google

of a county or large urban district, or also of having himself held appointment as Medical Officer of Health. He must also have regularly attended for six months the wards of a general fever hospital containing not less than fifty beds. Every candidate who is not a graduate in Medicine of this University must have attended a course of instruction in the University in one or more of the subjects embraced in the examination for the diploma. The diploma is conferred after an examination in Public Health held in March and July of each year. Candidates desiring to appear for examination at either of these periods must send in their names, with the necessary fee, to the Secretary of the Medical Faculty before the first day of the month in which the examination takes place. The fee for the examination is £5 5*s*. The examination is conducted by specially qualified examiners appointed by the University. Candidates may enter for the whole examination at one period, or they may enter for Parts I. and II. at one period and for Parts III. and IV. at another and subsequent period.

The Royal Colleges of Surgeons and Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.—All candidates for the diploma in Public Health must have been qualified for at least one year. Those qualified before 1890 and also those who have held the position of Medical Officer of Health to a county or to an urban district of more than 20,000 inhabitants, or an entire rural sanitary district, do not require to produce evidence of attendance on any special courses. All other candidates must have attended, after qualifying, six months' practical instruction in a recognised public health laboratory or laboratories, and must have studied for six months the duties of out-door sanitary work under the Medical Officer of Health of a county or large urban district, or must themselves have held an appointment as Medical Officer of Health under conditions not requiring the possession of a sanitary diploma. It is also recommended where possible to take out a course of instruction in the diseases of animals transmissible to man.

There are two examinations, and candidates may enter for both at one period or for either separately. The First Examination includes (*a*) Laboratory Work, (*b*) Chemistry, (*c*) Physics, and (*d*) Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 10 guineas for both examinations, or 5 guineas for either of them. The examination is held twice yearly, in May and October. The published regulations provide detailed synopses of the subjects of examination and give lists of books from which to select. The Registrar for Edinburgh is Mr. James Robertson, 48, George-square; and for Glasgow Mr. Alexander Duncan, 242, St. Vincent-street.

IRELAND.

Royal University of Ireland.—This University grants a diploma in Sanitary Science. It is conferred only on graduates in Medicine of the University. Candidates are not admitted to this examination until the lapse of twelve months from the time of obtaining the first registrable qualification; they must give notice in writing to the Secretaries of their intention to present themselves and must pay the fee, £2, at least one month previously to the examination. Candidates are required to produce a certificate of having, after obtaining the degree of M.B., B.Ch., B.A.O., attended six months' practical instruction in a laboratory approved by the University, and also of having for six months practically studied the duties of out-door sanitary work under the Medical Officer of Health of a county or large urban district.

University of Dublin.—The Diploma in State Medicine is conferred, after examination, on the following conditions:—The candidate must be a Doctor in Medicine, a graduate in Medicine and Surgery of Dublin, Oxford, or Cambridge. The name of the candidate must have been on the Medical Register at least twelve months before the examination. The candidate must have completed, subsequently to registration, six months' practical instruction in a laboratory approved by the University and also have studied practically out-door sanitary work for six months, under an approved officer of health. The subjects of examination will be—(*a*) State Medicine and Hygiene, including causation and prevention of disease, contagion in different diseases, morbid diathesis, congenital diseases and malformations, diseases of animals in relation to the health of man, diseases of the vegetable kingdom, famine diseases, causes of origin and spread of epidemics, principles of bacteriology, quarantine, disinfection &c.; (*b*) Chemistry, including air, water, and articles of food and drink, and their chemical and microscopical examination and analysis, the detection of common poisons and recognition of injurious pigments, &c.; (*c*) Physics and Meteorology; (*d*) Engineering; (*e*) Morbid Anatomy; (*f*) Vital Statistics; (*g*) Medical Jurisprudence; and (*h*) Practical Sanitary Engineering.

Royal College of Physicians and Royal College of Surgeons in Ireland.—Stated examinations for the diploma in State Medicine are held in the months of February, May, and November. A special examination for the diploma can be (except during the months of August and September) obtained on payment of £5 5*s*., in addition to the ordinary fees mentioned below, and on giving notice at least one fortnight before the date of the proposed examination. Every candidate for the diploma in State Medicine must be a registered medical practitioner. (Candidates registered or entitled to be registered prior to January, 1890, are exempt from the rules as to study.) He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man, and (2) during six months either practically study out-door sanitary work under a Medical Officer of Health or himself hold an appointment of Medical Officer of Health under conditions not requiring the possession of a special sanitary diploma. Candidates are examined on four days commencing on the first Tuesday of February, May, and November, and shall as an additional requirement attend a hospital for infectious diseases. Each candidate must return his name to the secretary of the committee of management under the conjoint scheme three weeks before the examination, and lodge with him a testimonial of character from a Fellow of either of the Colleges, or of the Royal Colleges of Physicians or Surgeons of London or Edinburgh. The fee for the examination is £10 10*s*. The examination for the diploma in State Medicine comprises the following subjects:—State Medicine and Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Law, and Bacteriology. For further particulars apply to the Secretary, Committee of Management Office, Royal College of Physicians, Dublin.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without the special licence; but it is of eminent advantage to take the L.D.S., otherwise few dental appointments at general or special hospitals or dispensaries are available, and, what is still more important, the manual dexterity and knowledge of mechanics requisite for the successful practice of dentistry can only be gained by long and careful training at the dental operating chair and in the dental laboratory; and, this having been attained, it costs but little trouble to pass the special examinations. The subjects beyond those included in the general qualification are—Dental Anatomy and Physiology (Human and Comparative), one course; a separate course of Dental Histology, including the preparation of microscopical sections; Dental Surgery, one course; a separate course of Practical Dental Surgery; a course of not less than five lectures on the Surgery of the Mouth; Dental Mechanics, one course; a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns; Dental Metallurgy, one course; a course of Practical Dental Metallurgy; Practice of Dental Surgery at a recognised school, two years, and a certificate of having been engaged during a period of not less than three years in acquiring a knowledge of Dental Mechanics (this may be obtained by apprenticeship to a duly qualified dental practitioner or in the mechanical department of a recognised dental hospital). In the case of qualified surgeons two years will suffice. The Dental Schools in London are the Dental Hospital of London, the National Dental Hospital and College, and Guy's Hospital Dental School. Most of the large provincial towns have now dental hospitals. A convenient arrangement by which the M.R.C.S., L.R.C.P., and L.D.S. can be taken is as follows:—The Preliminary Examination in General Education having been passed, the student should become apprenticed to a qualified dentist and register as a dental and medical student. (This instruction, however, may be taken prior to

Digitized by Google

the date of registration as a dental student.) During his apprenticeship the student should receive instruction in Chemistry and Physics, Pharmacy and Elementary Biology, and pass in these subjects before entering the hospital. (The foregoing constituting the First Examination.) Having entered the hospital, the student should attend the dental and general courses contemporaneously, and pass at the end of the second winter the Second Examination—namely, Anatomy and Physiology. At the completion of his second year of study the Dental Examination should be passed. The student should then devote his time to general studies, and pass the third examination. When time permits it is advisable to attend the general hospital only, until after the First and Second Examinations have been passed. At this point a break may be made to admit of the completion of the dental curriculum and the passing of the examinations for the L.D.S. diploma. The best course, however, is to entirely finish the curriculum for the M.R.C.S. and L.R.C.P. and then take the special Dental work. The regulations for the Dental Licence of the Royal Colleges of Ireland and Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow are very similar to those of the English College. The L.D.S. can also be obtained alone.

REGISTRATION OF DENTAL STUDENTS.

The registration of dental students is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations. Students who commenced their professional education by apprenticeship to dentists entitled to be registered, or by attendance upon professional lectures before July 22nd, 1878 (when dental education became compulsory), are not required to produce evidence of having passed a Preliminary Examination. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies, and of having received three years' instruction in Mechanical Dentistry from a registered practitioner. One year's *bonâ-fide* apprenticeship with a registered dental practitioner, after being registered as a dental student, may be counted as one of the four years of professional study. The three years of instruction in Mechanical Dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student; but no year of such mechanical instruction will be counted as one of the four years of professional study unless taken after registration.

It is now necessary for anyone practising Dental Surgery in this country to register, and no foreign qualifications are admitted. Formerly exception was made with regard to the Universities of Harvard and Michigan.

The Royal College of Surgeons of England grants a diploma in Dental Surgery under the following regulations, which apply to all Candidates who have registered as Dental Students after Jan. 1st, 1897. Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. I. Preliminary Science Examination. Before admission to this examination the Candidate must produce a certificate of having received instruction (which may be taken prior to the date of registration as a dental student) at a recognised institution in Chemistry, Physics, and Practical Chemistry. The examination consists of these subjects, and is identical with Part I. of the First Examination of the Examining Board in England. II. The First Professional Examination. The Candidate must produce the following certificates:—1. Of having been engaged during a period of not less than three years in acquiring a practical familiarity with the details of Mechanical Dentistry, under the instruction (which may be taken prior to registration as a dental student) of a competent Practitioner or under the direction of the Superintendent of the Mechanical Department of a recognised Dental Hospital. In the case of qualified surgeons, evidence of a period of not less than two, instead of three, years of such instruction will be sufficient. 2. Of registration as a dental student by the General Medical Council. 3. Of having attended at a recognised Dental Hospital and School (*a*) a course of lectures on Dental Metallurgy; (*b*) a course of Practical Dental Metallurgy; (*c*) a course of Lectures on Dental Mechanics; and (*d*) a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns. Candidates may present themselves for the First Professional Examination after the completion of six months' attendance at a recognised Dental Hospital and School. The Examination consists of Mechanical Dentistry and Dental Metallurgy; the examination in Dental Metallurgy will be by written paper. III. The Second Professional Examination. The Candidate must produce the following certificates:—1 Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a dental student. 2 Of having attended at a recognised dental hospital and school (*a*) a course of Dental Anatomy and Physiology; (*b*) a separate course of Dental Histology, including the preparation of microscopical sections; (*c*) a course of Dental Surgery; (*d*) a separate course of Practical Dental Surgery; and (*e*) a course of not less than five lectures on the Surgery of the Mouth, which lectures may be given at a dental hospital or at a recognised medical school; in the latter case they may form part of the course of lectures on Surgery. 3. Of having attended at a recognised dental hospital or in the dental department of a recognised general hospital the practice of Dental Surgery during two years. 4. Of having attended at a recognised medical school (*a*) a course of lectures on Anatomy, (*b*) a course of lectures on Physiology, (*c*) a separate Practical Course of Physiology, (*d*) a course of lectures on Surgery, and (*e*) a course of lectures on Medicine. 5. Of having performed Dissections at a recognised medical school during not less than twelve months. 6. Of having attended at a recognised hospital the practice of Surgery and Clinical Lectures on Surgery during two winter sessions. 7. Of being twenty-one years of age. The certificates of professional study will be required to show that students have attended the courses of professional study to the satisfaction of their teachers. Candidates may present themselves for the Second Professional Examination after the completion of four years' professional study from the date of registration as a dental student and after the lapse of not less than six months from the date of passing the First Professional Examination. The Second Professional Examination consists of General Anatomy and Physiology, General Surgery and Pathology. Dental Anatomy and Physiology, Dental Pathology and Surgery, and Practical Dental Surgery. The written examination comprises General Anatomy and Physiology, General Pathology and Surgery, Dental Anatomy and Physiology, and Dental Pathology and Surgery. At the Practical Examination candidates may be examined (*a*) on the treatment of Dental Caries, and may be required to prepare and fill cavities with gold or plastic filling or material, or to do any other operation in Dental Surgery (candidates must provide their own instruments); (*b*) on the Mechanical and Surgical Treatment of the various Irregularities of Children's Teeth. There is also an oral Examination. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the second Examination of the Examining Board in England or the corresponding Examination of the Royal College of Surgeons of Edinburgh, the Royal College of Surgeons in Ireland, or the Faculty of Physicians and Surgeons of Glasgow, or of any University in the United Kingdom. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and Universities above mentioned. The fee for the diploma is 20 guineas, and is payable as follows:—Preliminary Science Examination, 3 guineas; First Professional Examination, 2 guineas; Second Professional Examination, 5 guineas; the balance to be paid on the completion of the Examinations. The Preliminary Science Examination is held in January, March or April, July, and October in each year. The first and second Professional Examinations are held in May and November in each year. Candidates must give twenty-one clear days' notice of their intention to present themselves for examination.

Royal College of Surgeons, Edinburgh.—For the licence in Dental Surgery all candidates must pass a preliminary examination in general knowledge and have their names inscribed in the Register of Dental Students of the General Medical Council. A copy of regulations, giving a list of preliminary examinations recognised for obtaining this licence, as well as of the subjects of the professional examinations, may be obtained from Mr. James Robertson, Clerk to the Royal College of Surgeons, at

Digitized by Google

48, George-square, Edinburgh. Students who commenced their professional education by apprenticeship or attendance on lectures before July 22nd, 1878, are exempt from the preliminary examinations. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies, and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates who have commenced their studies *after* Oct. 1st, 1890, must have attended the following curriculum: Anatomy, one course of six months; Practical Anatomy, twelve months; Chemistry, one course of six months; Practical Chemistry, one course of three months; Physiology, one course of six months; Materia Medica, one course of three months; Surgery, one course of six months: Medicine, one course of six months; and attendance on the practice of a recognised general hospital, with Clinical Instruction, twelve months. (Candidates who commenced study in accordance with the regulations in force before July, 1895, shall not be required to attend more than six months' hospital work.) These courses must have been attended at a University, or in an established school of medicine, or in a provincial school specially recognised by the College as qualifying for the diploma in Surgery. In addition to these courses candidates will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, the following special courses of lectures and instruction: Dental Anatomy and Physiology (Human and Comparative), Dental Surgery and Pathology, Dental Mechanics—one course each; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Certificates of attendance on such of these courses of the new curriculum as may be respectively required will entitle candidates to appear either for the first dental examination or for the first and second examinations for the triple qualification, as they may select, and subject to the existing regulations for each qualification. Candidates who have passed the first and second examinations for the triple qualification will be exempt from the first dental examination, and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the first and second Triple Examinations, and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College, or who may be registered medical practitioners, will be required to produce certificates of attendance on the special subjects only, and will be examined in these only for the Dental diploma. First Professional Examination: The candidate must have attended the courses on Anatomy, Chemistry, and Physiology. The examination embraces Anatomy, Chemistry, and Physiology. The fee is £4 4*s*. Second Examination: The candidate must have attended the remaining courses of the curriculum, must be twenty-one years of age, and must pay a fee of £6 6*s*. The examination embraces Surgery, Medicine, Therapeutics, and the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, and Dental Mechanics. Unsuccessful candidates will be repaid £2 2*s*. in the First and £3 3*s*. in the Second Examinations. Candidates who claim exemption from the First Dental Examination, on the ground of having passed the First and Second Triple Qualification Examinations, will, before being admitted to the Second Dental Examination, be required to pay the total fee of £10 10*s*., payable for the Dental diploma, of which £3 3*s*. will be returned in case of rejection. The fee payable by candidates who begin study after Oct. 1st shall be £15 15*s*.

Faculty of Physicians and Surgeons of Glasgow.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh. Special provision is made for candidates who intend to qualify both in Medicine and in Dentistry. There is a practical examination in Mechanical Dentistry and also an examination in Practical Dentistry conducted in a dental hospital.

Royal College of Surgeons in Ireland.—All information concerning the licence in Dentistry may be obtained from the Registrar of the College, who will receive the applications of candidates for permission to be examined. The bank receipt for fees, together with all certificates, &c., are to be lodged with him at least seven days prior to the day fixed for the commencement of the examination. The Primary Dental Examinations commence on the second Monday in the months of February, May, and November. The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations. Candidates are required to pass three examinations—viz., Preliminary (in General Education), Primary Dental, and Final Dental. Preliminary Examination.—All examinations in general education recognised by the General Medical Council are accepted by the College. Preliminary Examinations are held conjointly by the Royal Colleges of Physicians and Surgeons on the third Wednesdays in March and September. Primary Dental Examination.—Fee £10 10*s*.; for re-examination, if rejected, £5 5*s*. Every candidate[2] is required, before admission to the Primary Dental Examination, to produce evidence—(1) of having passed a recognised preliminary examination and of having been registered as a medical or dental student by the General Medical Council; (2) of having, subsequently to registration as a dental or medical student, attended at a recognised medical school the following courses: Lectures on Practical Anatomy, including Dental Anatomy, six months; Demonstrations and Dissections, two courses of six months each; Lectures on Chemistry, six months; Lectures on Physiology including Dental Physiology, six months; Practical Histology; and Practical Chemistry, including Metallurgy, three months; (3) of having attended Clinical Instruction at a recognised general hospital for one year. The subjects of this examination are: (1) Physics;[3] (2) Chemistry, including Metallurgy; (3) Anatomy; (4) Physiology and Histology; and (5) Surgery. Final Examination.—Candidates holding L.R.C.S.I., or students who have passed Primary Dental or Third Professional Examination of the College, £10 10*s*.; re-examination, £5 5*s*. Fees for Final Examination of all other candidates, £26 5*s*.; re-examination, £10 10*s*. Extra fee for Special Examination, £5 5*s*. Candidates must produce evidence of having passed the Primary Dental Examination of this College, or the Third Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, and are required to produce certificates of having attended: (1) the following courses of lectures recognised by the College: Dental Surgery and Pathology (two courses), Dental Mechanics (two courses); (2) for two years the practice of a dental hospital recognised by the College, or of the dental department of a general hospital so recognised; (3) of having been engaged during four years in professional studies; and (4) of having received three years' instruction in Mechanical Dentistry from a registered dentist. Candidates holding a diploma in Surgery shall be admissible to the Final Dental Examination on producing certificates of having attended: (1) one course of Lectures on Dental Surgery and Pathology; (2) one course of Lectures on Dental Mechanics; (3) for one year the practice of a Dental Hospital recognised by the College, or of the Dental Department of a General Hospital so recognised, where such attendance has been subsequent to the date of diploma (this remission (3) has been made on the understanding that the surgeon devotes his whole time to dental work); and (4) of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist. The following are the subjects of examination: Dental Surgery, Theoretical (including Dental Pathology), Clinical, and Operative; Dental Mechanics, Theoretical, Clinical, and Practical (including the Metallurgy of the workshop). Examinations for the Licence in Dentistry *sine curriculo*: The Council has power to admit to examination, *sine curriculo*, candidates whose names are on the Dental Register, published under the direction of the General Medical Council, and who are unable to furnish the certificates required by the foregoing regulations, on presentation of a special schedule of application.

---

[2] Candidates educated in England or Scotland are admitted to the Primary Dental Examination on the production of the certificates that would be necessary for both Primary and Final Examinations in their own countries.

[3] Candidates who have passed in Chemistry and Physics at a First Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination, recognised by the College, are exempted from examination in these subjects at the Primary Dental Examination.

TEACHING INSTITUTIONS.

ENGLAND.

Dental Hospital of London and School of Dental Surgery, Leicester-square.—The school was founded to provide the special dental education required by the Royal College of Surgeons for the licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 4 P.M., there being one staff for the morning and another for the afternoon of each day. There is a good mechanical laboratory, and opportunity is afforded students of gaining practical experience in taking models and fitting dentures into the mouth. The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for one year each, and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the mechanical laboratory. A scholarship of the value of £20 has been founded by Sir Edwin Saunders and will be awarded to the student who has obtained the highest aggregate number of marks in the five class examinations—viz., the four Lecturers' Prizes, the Operating Prize—and in additional special *viva-voce* examinations in Practical Dentistry. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses, at the end of the summer and winter sessions. A prize of the value of 5 guineas is given by Messrs. Ash and Sons for the best essay on some surgical subject connected with Dental Surgery. The conditions under which this prize is to be competed for are the same as those for the Saunders Scholarship, with this exception, that the papers are to be written in the hospital during the summer session. Consulting Physician: Sir Richard Quain, Bart., F.R.S., M.D., F.R.C.P., LL.D. Consulting Surgeon: Mr. Christopher Heath, F.R.C.S. Consulting Dental Surgeons: Mr. T. Arnold Rogers, M.R.C.S., L.D.S., and Mr. Smith Turner, M.R.C.S., L.D.S. Dental Surgeons: Leonard Matheson, L.D.S.; E. Lloyd Williams, L.R.C.P., M.R.C.S., L.D.S., L.S.A.; W. B. Paterson, F.R.C.S., L.D.S.; W. H. Woodruff, L.D.S. and A. Clayton Woodhouse, M.R.C.S., L.D.S. Assistant Dental Surgeons: J. F. Colyer, L.R.C.P., M.R.C.S., L.D.S.; C. F. Rilot, L.R.C.P., M.R.C.S., L.D.S.; H. Baldwin, M.R.C.S., L.D.S.; H. Lloyd Williams, M.R.C.S., L.D.S.; W. H. Dolamore, L.R.C.P., M.R.C.S., L.D.S.; Percy Smith, L.R.C.P., M.R.C.S., L.D.S.; G. Hern, L.R.C.P., M.R.C.S., L.D.S.; J. G. Turner, L.R.C.P., F.R.C.S., L.D.S.; Russell Barrett, L.R.C.P., M.R.C.S., L.D.S.; Ashley Densham, L.R.C.P., M.R.C.S., L.D.S.; N. G. Bennett, M.A., M.B., L.D.S.; and D. P. Gabell, L.R.C.P., M.R.C.S., L.D.S. Anæsthetists: Dudley W. Buxton, M.D., B.S. Lond., M.R.C.P. Lond.; Frederic W. Hewitt, B.A., M.D. Cantab.; Carter Braine, F.R.C.S.; and Henry Davis, M.R.C.S., L.S.A.; Assistant Anæsthetists: George Rowell, F.R.C.S.; E. A. Bridger M.D.; R. Turle Bakewell, M.B. Lond. L.R.C.P., M.R.C.S. Demonstrators: H. J. Stevens, L.D.S.; W. S. Nowell, M.A. Oxon, L.D.S.; H. Austin, M.D. Lond., L.D.S.; R. Herschell, L.D.S. Medical Tutor: D. P. Gabell, L.R.C.P., M.R.C.S., L.D.S.; Curator of Mechanical Laboratory: W. E. Fletcher. Lecturers.—Dental Anatomy and Physiology (Human and Comparative): Charles Tomes, F.R.S., M.A. Oxon, M.R.C.S., L.D.S., on Wednesdays and Saturdays, at 8 A.M. (Summer). Dental Surgery and Pathology: Storer Bennett, L.R.C.P., F.R.C.S., L.D.S., on Tuesdays and Fridays, at 8 A.M. (Summer). Mechanical Dentistry: E. Lloyd Williams, L.R.C.P., M.R.C.S., L.D.S., L.S.A., on Wednesdays, at 5 P.M. (Winter). Metallurgy in its Application to Dental Purposes: Dr. Forster Morley, M.A., F.I.C., F.C.S., on Thursdays, at 5 P.M. (Winter). During the sessions the surgeons of the day will give demonstrations at stated hours. The house surgeons attend daily while the hospital is open. Fee for two years' hospital practice required by the curriculum, including lectures, £50 in one payment, or 50 guineas in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £55. Both hospitals can be attended simultaneously. The Dean, Mr. Morton Smale, attends at the hospital every Wednesday morning from 10 to 12, and daily from 5 P.M. to 6 P.M. from Sept. 28th to Oct. 1st, and from April 29th to May 3rd, or he can be seen by appointment. Letters to be addressed—40, Leicester-square, "to be forwarded."

National Dental Hospital and College.—Winter Session, 1897–98, commences on Oct. 4th at the new building at the corner of Great Portland and Devonshire streets, W.—Consulting Physician: Sir W. H. Broadbent. Consulting Surgeon: Mr. Christopher Heath. Consulting Dental Surgeon: Sir Edwin Saunders. Honorary Visiting Physician: Dr. James Maughan. Honorary Visiting Surgeon: Mr. E. W. Roughton. Dental Surgeons: Mr. F. H. Weiss, Mr. A. Smith, Mr. M. Davis, Mr. T. G. Read, Mr. Rushton, and Mr. C. W. Glassington. Assistant Dental Surgeons: Mr. W. Weiss, Mr. E. Beverley, Mr. W. H. Wheatley, Mr. H. J. Relph, and (vacancy). Anæsthetists: Mr C. H. Cosens, Dr. Flux, Mr. C. J. Ogle, Mr. G. E. Norton, Dr. J. Maughan, and Dr. Harold Low. Lecturers (winter), Dental Anatomy and Physiology: Dr. J. W. Parc, Tuesdays and Thursdays, 5 P.M., in October, November, and December. Operative Dental Surgery: Dr. George Cunningham, Mondays, 6.30 P.M., in October, November, and December. Dental Materia Medica and Therapeutics: Mr. C. W. Glassington, Tuesdays, 7.30 P.M., in October, November, and December. Dental Metallurgy: Dr. W. Lapraik, Tuesdays, 7.30 P.M., in January, February, and March. Dental Mechanics: Mr. H. Rose, Mondays, 7 P.M., in January, February, and March. Summer—Dental Surgery and Pathology, Mr. Hopewell Smith, Mondays and Thursdays, 6 P.M., in May, June, and July. Elements of Histology: Dr. J. Maughan, Mondays and Thursdays, 5 P.M., May, June, and July. The hospital is lighted throughout by electricity and warmed and ventilated by approved methods. Clinical Lectures and Demonstrations are given from time to time, and each student on entering passes through a preliminary course under a demonstrator. The stopping rooms have accommodation for sixty chairs. Dresserships in the extraction rooms are rearranged every three months. An Entrance Exhibition, of the value of £15, is open for competition at the commencement of each summer and winter session. Prizes in medals are open for competition at the end of each course of lectures. Certificates of honour are given in each class. The Rymer Medal for General Proficiency, value £5, is awarded annually to the most meritorious student; and the Ash Prize, value £3 3*s.*, for a Thesis on a subject in Dental Surgery. Total fee for the Special Lectures and Hospital Practice required, 40 guineas. Single Courses: Dental Anatomy and Physiology, Dental Surgery and Pathology, Dental Mechanics, Dental Metallurgy, Dental Materia Medica, Demonstration of Dental Mechanics, £5 5*s.* each. Operative Dental Surgery, £3 3*s.* Hospital Practice to registered practitioners by special permission of Committee, twelve months, £15 15*s.* The Committee also consider applications from medical men who may desire to attend the Anæsthetic Room for a course of instruction in Nitrous Oxide administration. Information respecting the Hospital Practice and the College may be obtained from the Dean, Mr. Sidney Spokes, who attends at the Hospital, Great Portland-street, on Tuesday mornings.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. *The Extraction Rooms:* Patients are admitted between 9 and 10.30 A.M., and are seen by the dental surgeon for the day, the dental house surgeon, the assistant dental house surgeon, and the dressers. Such cases as are suitable for conservative treatment are transferred to the conservation room, taking with them a dental chart to indicate the treatment required. *The Conservation Room:* This room is open from 9 A.M. till 5 P.M. There are fifty Monson chairs for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and on certain afternoons in the week to give demonstrations and otherwise assist students in their work in the Conservation Room and Mechanical Laboratory. Dental students have the opportunity of attending concurrently at this hospital the two courses of instruction required by the examining board for the L.D.S. Eng., viz., the special lectures and practice of the Dental Department and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. An Entrance Scholarship in Arts of the value of £30 is offered for competition annually in September, and prizes of the

Digitized by Google

aggregate value of £35 are awarded for general proficiency and skill in Practical Dentistry. Dental students are eligible for admission to the Residential College and enjoy the other social privileges of students in the Medical School.

London Hospital.—Mr. Cunningham and Mr. Dolamore give practical instruction during the winter and summer sessions on Mondays, Tuesdays, Thursdays, and Fridays at 9 A.M. In selecting from candidates for the office of Dental Assistant priority will be given to those who have attended the greatest number of lectures on Dental Pathology and Surgery, and have also been the most punctual in attendance in the dental department. A class for special instruction in filling teeth will be formed each term. Candidates for Dressership must undertake to attend regularly on Mondays and Thursdays, or on Tuesdays and Fridays, for three months, and to follow the practical course of demonstrations.

Mason College, Birmingham.—The teaching of Dentistry is undertaken by the Mason College, acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board, so that the students may fully qualify themselves for the Dental diploma of the Royal Colleges. There is a special and well-equipped Dental Museum and Laboratory. Special courses of lectures are delivered on Medical and Surgical Diseases of the Mouth, &c., and there is a special course of Practical Dental Histology and Pathology. An Entrance Exhibition, value £15 15*s*, is awarded annually at the commencement of the winter session. Medals and honour certificates are awarded annually in the various classes.

Liverpool Dental Hospital, Mount Pleasant.—The Liverpool Dental Hospital, founded in the year 1864, combines the work of a most useful charity with all the advantages of a dental school recognised by all the licensing bodies of Great Britain and Ireland. The increased facilities provided by the recent extensive additions and alterations have more than fulfilled the most sanguine anticipations of the committee and staff, and students have been quick to avail themselves of the increased accommodation and conveniences. Special attention has been paid to the ventilation and lighting; the electric light alone is employed for operating during the evening. Each chair has been provided with a specially constructed canting pendant which can be fixed at any angle. The chairs are of the well-known Morrison pattern, which, together with other fittings and fixtures, render this room one of the finest in the kingdom. There is an abundant daily supply of patients. Over 23,000 cases were treated during last year. The hospital staff consists of twelve honorary dental surgeons, one of whom is present each morning and evening. In addition to these there are one or more house surgeons to superintend all the hospital work and devote themselves to clinical teaching, advising and helping the students in their studies. Every facility is afforded to students who are anxious to acquire proficiency in Dental Surgery and to prepare themselves for the Dental diploma of the Royal College of Surgeons. The fee for the two years' Dental Hospital Practice required by the Royal College of Surgeons is £12 12*s*., which must be paid on entrance. Fee as a perpetual student, £15 15*s*. Composition fee for all Lectures: a payment of £50 on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months). Fee for General Hospital Practice, £10 10*s*. All communications relating to the medical department should be addressed to Professor Paterson, Dean of the Medical Faculty, University College; and all communications relating to the Dental Hospital should be addressed to R. Edwards, 50, Mount Pleasant.

Bristol General Hospital.—Mr. Genge gives practical instruction in Dental Surgery at 9.30 A.M. on Mondays and Thursdays.

University College, Bristol.—Dental Students can enter for the full curriculum at Bristol. The Lectures are delivered at the college. Practical instruction is given at the Royal Infirmary by Mr. Ackland and at the General Hospital by Mr. Genge, both institutions being recognised by the Dental Board of the Royal College of Surgeons of England. Full information may be obtained of the Dean of the Medical Faculty, Professor E. Markham Skerritt, University College, Bristol.

Owens College, Manchester.—Arrangements have been made for dental students to attend the hospital practice at the Manchester Royal Infirmary and the practice at the Victoria Dental Hospital. Lectures on special subjects will be given in the College as follows:—Winter session: Dental Mechanics, Mr. Tanner, Thursday, 4 P.M. Dental Metallurgy, Dr. Burghardt. Summer session: Dental Anatomy and Physiology, Mr. Hooton, Tuesday at 4 P.M., Friday at 2 P.M. Dental Surgery, Mr. Campion, Tuesday and Friday, 3 P.M. Practical and Operative Dental Surgery, Mr. Whittaker, Wednesday: Lecture, 2.30 P.M.; Demonstration, 4 P.M. Lectures in Dental and Practical Histology, Mr. Headridge. Fee for the course £4 4*s*. Dental practice for two years at the Manchester Royal Infirmary, £10 10*s*.; at the Victoria Dental Hospital at Manchester, £12 12*s*., paid in advance, or £8 8*s*. for the first year and £5 5*s*. for the second year. At the Victoria Dental Hospital patients attend at 8.30 A.M. daily, and at 7 P.M. on Monday, Wednesday, and Friday. Consulting Physicians: Dr. H. Simpson and Professor D. J. Leech. Consulting Surgeons: Mr. E. Lund, Mr. F. A. Heath, Professor T. Jones, and Mr. J. Hardie. Consulting Dental Surgeons: Mr. H. Campion and Mr. G. W. Smith. Dental Surgeons: Mr. G. G. Campion, Mr. E. P. Collett, Mr. W. Dougan, Mr. L. Dreschfeld, Mr. J. W. Dunkerley, Mr. W. Dykes, Mr. W. Headridge, Mr. W. A. Hooton, Mr. I. Renshaw, Mr. W. Simms, Mr. W. Smithard, Mr. T. Tanner, and Mr. G. O. Whittaker. Assistant Dental Surgeons: Mr. P. A. Linnell, Mr. F. W. Minshall, Mr. C. R. Morley, and Mr. C. H. Smale. Administrators of Anæsthetics: Dr. A. Wilson and Dr. J. P. Stallard. Dean: Mr. G. G. Campion.

University College, Liverpool, School of Dental Surgery.—There is a school of Dental Surgery in connexion with the Medical Faculty. The curriculum includes Lectures and Demonstrations on all the subjects required for the licences in Dental Surgery of the Royal Colleges of England, Edinburgh, and Dublin, and of the Faculty of Physicians and Surgeons of Glasgow. In addition, Laboratory courses are conducted in Dental Histology and Dental Pathology. Practical instruction in Dentistry is given at the Dental Hospital in Mount Pleasant. Fees:—A payment of £50 on entrance, or in two equal instalments (one-half on entrance and the remainder within twelve months), entitles the student to attendance on all lectures and demonstrations (medical and dental) required for the Dental Diploma of the Royal College of Surgeons. The fee for two winters' hospital practice at the Royal Infirmary is £10 10*s*., and for two years' dental hospital practice £12 12*s*. Further information can be obtained from the Dean of the Medical Faculty, Professor Paterson, University College, Liverpool.

Devon and Exeter Dental Hospital, Castle-street, Exeter.—Established 1880.—The hospital is open daily (Sundays excepted), and patients are admitted between the hours of 9 and 11 A.M. Students attending the practice of the hospital must consider themselves strictly under the control of the medical officers, and must not undertake any operation without the consent of the dental surgeon for the day. Hon. treasurer, Mr. J. M. Ackland; Hon. secretary, Mr. Henry Yeo.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School, 31, Chambers-street, Edinburgh.—For the special classes, both theoretical and practical, required by dental students the directors have secured the services of an efficient staff of dental officers and lecturers. There will also be a course of demonstrations in Mechanical Dentistry. Students will receive instruction in Practical Dental Mechanics under the mechanician. The fee for clinics in gold filling is included in the Dental Hospital fee of £15 15*s*. The minimum cost of classes for the whole course of dental instruction amounts to £78 13*s*.

Dental Hospital and School, Glasgow.—The summer session was opened on May 4th, 1897, and the lectures were delivered as under:—Dental Surgery and Pathology, on Tuesdays and Thursdays, at 8 A.M. J. M. MacMillan, L.R.C.S. & P. Ed., L.D.S., lecturer. Dental Anatomy and Physiology, on Tuesdays and Fridays, at 7 P.M. Dr. Wm. Wallace, M.A., M.B., C.M., L.D.S., lecturer. The winter session opens on Nov. 2nd, 1897, and the lectures will be delivered as under: Dental Mechanics, on Tuesday evenings at 7 P.M., beginning Nov. 3rd. Mr. John A. Biggs, L.D.S., lecturer. Fee for each of the above courses of lectures, £3 3*s*. The lectures on Dental Anatomy and Dental Surgery are arranged to extend over two summer sessions, as required by the Royal College of Surgeons of England, thus enabling students to present themselves for examination at any of the four Licensing Boards. The fees for lectures and two years' hospital practice amount to £25 4*s*. Intending students before commencing to attend the lectures or hospital practice must produce evidence of having passed the preliminary examination prescribed by the regulations of the General Medical Council for registration of dental

Digitized by Google

students. Dean: Mr. John A. Biggs. Secretary: D. M. Alexander, 97, West Regent-street, Glasgow. The hospital is open daily from 5 to 7 P.M. (Saturdays excepted). Students may enrol at any time, their period of attendance counting from date of entry.

Glasgow Royal Infirmary (Dental Department).—Mr. W. H. Gray, L.D.S., attends at the Royal Infirmary at 3 P.M. on Mondays, Wednesdays, and Saturdays, and gives a course of Dental Surgery on these days in summer. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. The attendance on the Dental Clinic is free to students of the hospital; to dental students, one year, £5 5*s.*; perpetual, £10 10*s.*

IRELAND.

School of the Royal College of Surgeons in Ireland.—Dentistry Professor: R. T. Stack, M.D.Univ Dub., F.R.C.S., L.D.S. Eng., Examiner Royal College of Surgeons, Dentist Dental Hospital of Ireland. Arrangements are completed for the education of candidates for the Licence in Dental Surgery of the College, and the following courses are delivered during the session:—Dental Anatomy, Professor Fraser; Dental Metallurgy, Professor Lapper. Fee, each course, £3 3*s.*

Annotations.

"Ne quid nimis."

THE POSITION OF PSYCHOLOGY IN THE MEDICAL CURRICULUM.

As there is no hard-and-fast line between physiology and psychology it follows that in an indirect way psychology is a subject upon which every medical student receives some instruction and in his knowledge of which he must expect to be tested. What is familiarity with the symptoms of many cerebral conditions but psychological knowledge? The universities demand more knowledge of the subject than the licensing bodies, but London University enjoys the distinction of being the only examining body in the United Kingdom which definitely proposes to test by examination the knowledge of their students in this subject as a separate subject. For the study of psychology with an eye on the pass list there are no books so entirely satisfactory as "The Outlines of Psychology" and "The Teacher's Note-book of Psychology," by Professor James Sully, who has served as an examiner in mental and moral sciences at the Universities of Cambridge, London, and Victoria. In Dr. Savage's "Manual of Insanity" will be found special chapters dealing with this subject in its relation to insanity. That the student will generally pick up in the course of his reading upon other subjects sufficient knowledge of practical psychology to enable him to employ psychological knowledge in the affairs of life, when necessary, is undoubted. But knowledge so obtained is apt to be disorderly, the facts hard to find, and the deductions hard to draw. Therefore we strongly recommend every medical student during his last year of study to make a point of reading at least one of the two hand-books we have mentioned.

REPORTED CHOLERA IN BETHNAL GREEN.

AT this season of the year the very name of cholera is enough to strike terror into the minds of most people. Until recently we had not heard of any cases, but an inquest was held on Saturday last in Bethnal-green which, as reported in the daily press, might give rise to some misgivings. The case put shortly was that of a girl, aged seventeen years, employed in paper-sorting, who was taken ill at 1 A.M. and died at 5 P.M., being much collapsed and having suffered from acute vomiting and purging. Medical evidence was given to the effect that the girl died from English cholera, and the jury returned a verdict to that effect. In the reports which we have seen in the lay press the word English was omitted, which naturally makes the case seem more suspicious. We have the best authority for saying, however, that the case was one of English cholera, a disease which is not so uncommon in the summer as many people think, and that the bacteriological examination which has been made quite confirms this view. The recent very hot weather has given rise to a large amount of diarrhœa, and during the month of July the deaths in London from this cause were ninety-nine above the average, while the returns for the first two weeks of August show 575 and 621 deaths from this cause. With the return of cooler weather the diarrhœa death rate will probably decrease, and at present no uneasiness need be felt as regards an outbreak of Asiatic cholera.

SOME OF THE CHIEF APPOINTMENTS HELD BY MEDICAL MEN.

Medical Officer to the Local Government Board.—This appointment is in the hands of the President of the Local Government Board for the time being, and has hitherto been filled by the promotion of one of the two assistant medical officers of that Board.

Medical Inspectors of the Local Government Board.—These appointments also are made by the President of the Local Government Board. Qualification and experience in public health are taken into consideration.

Medical Officers to Poor-law Districts.—These appointments are made by the guardians of the union or parish in question, subject to the approval of the Local Government Board, which approval is primarily concerned with the medical and surgical qualifications of the persons appointed and the locality of their residences.

Public Vaccinators.—The conditions of appointment are the same as those already described for medical officers of Poor-law districts.

District Medical Officers of Health.—The appointments are made by the urban or rural district council in question, subject to the sanction of the Local Government Board, which sanction takes account of statutory qualifications, salary, area of district, &c.

County Medical Officers of Health.—The appointments are made by the respective county councils, with whom the question in all its details absolutely rests.

Lord Chancellor's Visitors in Lunacy.—There are two Visitors in Lunacy nominated by the Lord Chancellor. The appointments are usually bestowed on gentlemen who have distinguished themselves in the specialty.

Prison Medical Service.—Two medical officers are attached to each of the "first-class" prisons and one to several of the larger "second-class" prisons. They are required to devote their whole time to their official duties. The service is a small one and vacancies do not often occur. Forms of application can be procured from the Secretary to the Prison Department at the Home Office. The salary commences at £250 per annum, with free quarters, or an allowance in lieu thereof.

Medical Officers of the Mercantile Marine.—The Merchant Shipping Act, 1894 directs (Section 209) that every foreign-going ship having 100 persons or upwards on board shall carry a duly qualified medical practitioner. Ship's medical officers, however, are more often appointed under the part of the same Act relative to "emigrant ships." For the purposes of the Act an emigrant ship is defined as one which carries more than fifty steerage passengers, and a steerage passenger is defined as one who is not a cabin passenger. Section 303 provides that a medical practitioner shall be carried on board an emigrant ship where the number of steerage passengers exceeds fifty, and also where the number of persons on board (including cabin passengers, officers, and crew) exceeds 300. A medical practitioner shall not be considered to be duly authorised for the purposes of this Act unless (*a*) he is authorised by law to practise in some part of Her Majesty's dominions,

Digitized by Google

or in the case of a foreign ship in the country to which that ship belongs; and (*b*) his name has been notified to the emigration officer at the port of clearance, and has not been objected to by him; and (*c*) he is provided with proper surgical instruments to the satisfaction of that officer. If any person proceeds or attempts to proceed as medical practitioner in any emigrant ship without being duly authorised, he shall be liable to a fine not exceeding £100. Surgeons in charge of passenger ships should keep a record of any sickness that occurs on the voyage, whether among saloon passengers, emigrants, or crew, and they are requested to report the same to the emigration officer at the end of the voyage. The remuneration for these appointments is extremely variable, ranging from a free passage to the port of destination to a salary of £10 a month during continuance in the service. The appointments are of course made by the various firms of shipowners and the applicants are sometimes numerous.

FACILITIES FOR CLINICAL INSTRUCTION IN INFECTIOUS DISEASE AFFORDED BY THE HOSPITALS OF THE METROPOLITAN ASYLUMS BOARD.

THE study of infectious disease is a very necessary part of the student's curriculum, but it is only within recent years that proper facilities have been afforded for taking advantage of the valuable material to be found in the fever hospitals of the Metropolitan Asylums Board. In former years the student had but few opportunities of becoming familiar with the natural history of this branch of medicine, and it was by no means an unheard-of event for a student to complete his career without having seen half a dozen cases of infectious disease. That there is still evidence of the state of affairs which formerly obtained may be gathered from the fact that during 1895 no fewer than 1277 patients, or a percentage on the total admission into the Metropolitan Fever Hospitals of 7·6, were, after admission, found not to be suffering from the diseases mentioned in the medical certificates upon which they were removed to hospital, the percentage of mistakes at the Eastern Hospital at Homerton being 11·0 of the total admissions. At the present time five of the admirable hospitals of the Asylums Board—viz., the Eastern at Homerton, the Western at Fulham, the South-Eastern at Deptford, the South-Western at Stockwell, and the North-Western at Hampstead, are open under certain conditions to students and medical practitioners, while instruction in small-pox is also afforded at the small-pox ships in the Long Reach, near Dartford. A student desirous of taking a course at one of the Board's hospitals, must have completed his third year and have held the office of clinical clerk and dresser; he must then obtain the sanction of the Medical School to which he belongs and pay a fee of three guineas for the first three months, and one guinea for each subsequent month to the clerk of the board, from whom he receives a card indicating the hospital to which he is to be attached. At this hospital he must attend at stated times for at least two days in the week for a minimum period of two months, and on the completion of his attendance he receives a certificate from the medical superintendent whose lectures and classes he has attended. While in the hospital the student places himself under the control of the medical superintendent, and is bound to observe the regulations in force for the prevention of spread of infection. These rules comprise the wearing while within the hospital wards of brown holland overalls, consisting of coat, trousers, and cap, which are provided by the board, and the use of what may be termed a discharge block, which consists of an infected room where the overalls are left, a lavatory, and a theoretically uninfected room. The students are further required to keep their hair short and to be efficiently protected against small-pox. A duly qualified medical practitioner has equally to conform to these regulations and obtain the consent of the medical superintendent of the hospital at which he elects to attend. The student who attends these courses will obtain a fair knowledge of infectious disease, which will stand him in good stead in years to come, while he will also get an insight into the management of fever hospitals and the methods of disinfection practised therein.

The provisions with regard to instruction in small-pox differ somewhat from the above, as it is necessary for the student to reside for from two to four weeks on the small-pox ships, where he is provided with rations, apartments, and washing at the extremely moderate sum of 12*s.* per week. The student has to travel to and from the hospital ships on the ambulance steamer and to furnish himself with a suit to which he does not attach much value, in order that it may be disinfected or destroyed at the termination of the period. If the student can take this course during the summer we can promise him, as the result of a personal experience, a most enjoyable and instructive little holiday.

MEDICAL TEACHERS.

MR. R. C. B. KERIN, B.A. London, first in First Class Honours in Classics, assisted by a staff of B.A. and B.Sc. Honour Graduates, prepares candidates in class and by private Tuition for Medical Preliminaries, London Matriculation, Preliminary Scientific Inter. Science, Hospital Scholarships, First Conjoint, First M.B. Oxon. and Camb., &c. Chemical and Physical Laboratories. For last four years 91 London University Successes and 3 Hospital Science Scholarships, &c.—Carlyon College, 55 and 56, Chancery-lane, W.C.

The University Examination Postal Institution prepares candidates through the post or personally for all medical examinations. The four medical tutors have the M.D. or M.S. degree, three being medalists. Preparation also by the other tutors for the Preliminary Arts or Science Examinations. Bacteriological Laboratory for D.P.H. candidates. Numerous recent successes.—Apply to the Manager, Mr. E. S. Weymouth, M.A. Lond., Office, 27, Southampton-street, Strand, London, W.C.

M.D., B.S. Lond., prepares for all the Professional Exams. Small classes are held for the Final College of Surgeons and Physicians, the Hall, the M.D.'s of Brussels, Durham (fifteen years' standing), Tuition by correspondence.—Address, M.D., 23, Wimpole-street, Cavendish-square, W.

Special preparation, in class, privately, and by correspondence, for the Triple Qualification, Edinburgh. Also for Fellowship Examinations of Royal College of Surgeons, Edinburgh, and M.D. Brussels. Resident pupils received.—Address, Class Rooms, 7, Chambers-street, Edinburgh.

Coaching for Examination (University of Brussels). Also Correspondence Course for Provincial Practitioners, with practical and vivâ voce work in London before going to Brussels.—Cantab., THE LANCET Office, 423, Strand, W.C.

INSTRUCTORS IN ELOCUTION, &c.

Professor ALTSCHUL, Ph.D., has made Stammering, Stuttering, Lisping, Falsetto, recent or of long standing, due to nervousness, &c., irrespectively of age or sex (without any mechanical appliances), his special life-long study. The voice greatly developed and strengthened.—9, Old Bond-street, W. (Attends at Brighton.)

Mr. WILLIAM VAN PRAAGH, the public introducer of the Pure Oral System of Teaching Deaf Mutes, has made the subject of Lip-reading and the cure of all Defects of Speech, both acquired and congenital, his special study. Papers on the various subjects can be had at 11 Fitzroy-square, W.

Mrs. EMIL BEHNKE gives instruction in Voice Training and treats Stammering and other Defects of Speech at 18, Earl's-court-square, S.W.

Miss BOULTBEE, 37, Gloucester-place, Portman-square, W., gives Lessons in Lip-reading to persons wholly or partially Deaf.

THE SERVICES.

WE are frequently asked for copies of the examination papers set at the competitive examinations of Her Majesty's Army and Indian Medical Services, and the following papers set at a recent examination may be of service to our readers. We omit the questions in Natural Science, which are more or less elementary. Three hours are allowed for each paper.

MEDICINE AND PATHOLOGY (PROFESSOR MCCALL ANDERSON).

1. State fully what the symptoms in the following case imply, giving the grounds for your diagnosis; and what anatomical lesions would you expect to find in the event of a fatal issue:—

A baker, aged twenty-six, whose family and personal history in early life were good, was admitted into hospital on Jan. 1st, 1897. Six years before, after a chill, he was seized with fever, profuse sweating, and pain and swelling in many joints, large and small. The joint affection was erratic—flitting about from joint to joint—but when he recovered their shape and mobility were in no way impaired. Three years thereafter—having in the interval apparently enjoyed excellent health—he began to suffer in an increasing degree from breathlessness and palpitation on exertion, sometimes accompanied by præcordial pain. On examining the heart the apex beat was found to be displaced considerably downwards and to the left of the nipple line, with a corresponding increase of the cardiac dulness, and there was a murmur at the apex accompanying the first sound, with accentuation of the second pulmonary sound at the base. Three months before admission he became suddenly paralysed on the right side, without loss of consciousness. The palsy of the arm and leg was nearly complete, that of the face partial, and mostly of its lower segment. At the same time he entirely lost the power

Digitized by Google

of speech, although he could read quite well, and understand everything that was said to him. A few weeks later the following symptoms gradually supervened on the paralysed side: increasing rigidity, tremors on exertion, exaggerated deep reflexes, and occasional spasms of the affected limbs.

2. How can hæmaturia be diagnosed, and what would lead you to suspect that the lesion was in the bladder and not in the urethra or upper urinary passages?

3. Describe the symptoms consequent upon a lesion involving the whole of the right internal capsule, and state what you know of "conjugate deviation" of the head and eyes and of "early" and "late rigidity."

4. How would you treat—(*a*) Passive congestion of the system due to dilatation of the heart; (*b*) the "night sweats" of phthisis; (*c*) myxœdema?

ANATOMY AND PHYSIOLOGY (MR. MAKINS).

1. Describe the triangular ligament of the urethra. State how it is formed and what structures are in relation with it.

2. Describe the form, position, and relations of the spleen. What theories exist as to its function.

3. Describe the structure of heart muscle. Give an account of the theories of its rhythmical contraction.

4. Give the course and distribution of the plantar nerves.

SURGERY (SIR WILLIAM MACCORMAC, BART.).

1. Give the causes, pathology, and treatment of ankylosis of the temporo-maxillary articulation.

2. What causes may induce hæmaturia of vesical origin. Omitting operative details, give the diagnosis and treatment.

3. Give the pathology, symptoms, diagnosis, and treatment of carcinoma of the large intestine. Illustrate your remarks by an example of the disease affecting the sigmoid flexure.

4. Enumerate the causes which may produce thrombosis of the brachial artery, and give the pathology, symptoms, and treatment.

CHEMISTRY AND MATERIA MEDICA (DR. NORMAN MOORE).

1. Describe an experiment by which the presence of carbonic acid in expired air may be demonstrated.

2. How is chlorine made? What are its properties?

3. What are the preparations of opium in the Pharmacopœia, and what proportion of opium does each contain?

4. Mention the chief anthelmintic drugs of the Pharmacopœia. State the method of administering each and the dose of each for an adult.

5. What drugs affect the quantity of the urine, and what drugs affect its physical characters?

THE BENEVOLENT AGENCIES OF THE PROFESSION.

ALL who belong to the medical profession should support the benevolent societies which minister to those in need in that profession, but students may rightly think that the support of such charities as well as their management should be left to their seniors; for whereas most students look to their friends and guardians for pecuniary support, to invite them to contribute to these medical charities is to ask their seniors to add to the subscriptions which they already send. But nowadays a fairly large section of the medical students, we think, are older men possessing independent means. To the notice of these we beg to bring the charities of the profession. All do good work on small incomes, all want further support, and all are economical in their management.

Before mentioning the general benevolent societies of the profession who ask for aid we may perhaps be pardoned if we direct attention to

THE LANCET RELIEF FUND,

founded in 1889 by the proprietors of THE LANCET. Year by year in the month of January the proprietors of THE LANCET provide a sum of at least £300, which is administered free of cost, for the purpose of affording immediate pecuniary assistance to medical men, or their widows and orphans, *in cases of distress and emergency*, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require. The fund has for its almoners the Presidents of the Royal Colleges of Physicians of London and Surgeons of England, the President of the General Medical Council, and the Proprietors of THE LANCET, with Sir Henry Pitman, M.D., F.R.C.P., as the honorary auditor. Applicants must satisfy the almoners of the fund that they are qualified under the following regulation: "The recipients shall be such persons as satisfy the almoners that they possess one or other of the following qualifications—that is to say: (*a*) That the applicant holds a registered medical qualification, and that he has fallen into pressing need of immediate pecuniary relief; or (*b*) that they are persons who have been, previously to the date of application, legitimately dependent upon some person holding a registered medical qualification, and that they have pressing need of immediate pecuniary relief." Application forms may be obtained from the secretary. Mr. Edward Davies, THE LANCET Offices, Strand, London, W.C.

THE BRITISH MEDICAL BENEVOLENT FUND.

The objects of this fund are twofold: (*a*) for the relief of medical men in temporary difficulty or distress and for their widows and orphans; and (*b*) for granting annuities to those who are quite incapable of providing for themselves after sixty years of age. Subscriptions for these objects may be sent to the treasurer, Sir W. H. Broadbent, Bart., M.D., F.R.C.P. Lond., 84, Brook-street, Grosvenor-square, W.; Dr. Samuel West, hon. financial secretary, 15, Wimpole-street, W.; and Mr. Joseph White, hon. secretary (cases), 6, Southwell-gardens, Kensington, S.W. The committee meet on the second Tuesday of every month except August. Applications are made by means of a form, which, when filled up by or on behalf of the applicant, must be signed by a subscriber (subscribers of 10*s.* and upwards and donors of £5 in one sum are entitled to this privilege), and should be sent, together with two or more letters of recommendation (one of which at least must be from a medical man), to Mr. Joseph White, on or before the Friday previous to the meeting of the committee. Forms of application for immediate relief may be obtained from any of the hon. secretaries.

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

This College was established in 1855 to provide pensions for aged medical men and the widows of medical men in reduced circumstances. The school is open to all classes, but the sons of medical men receive special advantages. There are fifty pensioners, who receive annuities of £30, with the exception of a few still occupying rooms in the asylum, who receive £21. There are also eight Pugh pensioners, who receive £30 a year each. There are also annuities for aged daughters of medical men. Pensioners must be legally qualified medical men, who have been for five years registered medical practitioners, or the widows of such. They must not be less than sixty years of age at the time of their application for admission as candidates, and their yearly income must not exceed £60. The school, generally known as "Epsom College," contains about 250 pupils, 50 of whom, being the Foundation scholars, are educated, boarded, clothed, and maintained at the expense of the institution; while the remainder are charged £60 a year each for an education of the highest class, board, lodging, and washing. Boys who are not the sons of medical men pay £70 a year. There are also day scholars; boarders in the headmaster's house, and a few (six under fifteen years of age) are taken by Mr. E. Norman Gardiner. For school prospectus apply to the bursar at the College, Epsom. Foundation scholars must be elected from among the necessitous orphans and sons of such medical men as would be professionally qualified for pensionerships. They must be fully eight years old when proposed as candidates, but no boy can be elected on the Foundation whose age exceeds twelve years on May 1st preceding the date of election. There are nine perpetual presentations for female orphans of medical men and one open to those who are not orphans to the school of St. Anne's Society. Donors of ten guineas are life governors of the College; subscribers of one guinea annually are governors during the continuance of their subscriptions. All subscriptions are due in advance on Jan. 1st in each year. Any information with regard to the details of the institution will gladly be communicated to parties addressing inquiries to the secretary, Mr. J. B. Lamb, at the office of the College, 37, Soho-square, where subscriptions and donations will be thankfully received. Subscriptions will also be received by the treasurer, Dr. Constantine Holman, J.P.

SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

This society is really a provident as well as a benevolent one. By the small annual subscription of two guineas members are able, should necessity unfortunately arise, to protect their own families from destitution, and benefits are conferred upon those left in indigent circumstances. All legally qualified members of the profession residing within a radius of twenty miles from Charing-cross are eligible for proposal; the mode of admission is by ballot. Proposal papers and other communications for the court of directors should be sent to the secretary three weeks before the first Wednesday in the months of January, April, July, and September. Further information can be obtained from the secretary, Mr. J. B. Blackett, at the office, 20, Hanover-square, W.

OUR CURRENT NUMBER

Being almost exclusively devoted to information especially interesting to Students, we are necessarily compelled to defer the publication of communications on other important subjects.

We tender our best thanks to those gentlemen who have at considerable personal trouble kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET *relative to the various medical examining bodies, hospitals, and medical schools of the United Kingdom is based. We regret that in some cases, however, owing to proofs having been either not returned at all or too late, certain inaccuracies will be found.*

TO ADVERTISERS.

Owing to the pressure on our advertisement columns this week many announcements have unavoidably been held over.

Communications, Letters, &c., have been received from—

A.—Dr. J. Altschul, Lond.; Messrs. Allen and Hanburys, Lond; Anglo-Swiss Condensed Milk Co., Lond.; Anderson's College Medical School, Glasgow, Secretary of; Mr. J. W. Arrowsmith, Bristol; Messrs. Armour and Co., Lond.

B.—Mr. D. T. Bostel, Lond.; Messrs. E. Bing and Son, Canterbury; Messrs. Brady and Martin, Newcastle-on-Tyne; Dr. O. Beven, Newark; Surg.-Capt. W. J. Buchanan, Buxar, India; Mr. E. A. Barton, Lond.; Mr. E. T. A. Boyton, Lond.; Dr. H. Charlton Bastian, Lond.; Mr. E. P. Baumann, Switzerland; Mr. C. J. Bennetts, Cornwall; Barony Parish Council, Glasgow, Clerk of; Blackburn and East Lancashire Infirmary, Secretary of.

C.—Prof. W. H. Corfield, Lond.; Chelsea Hospital for Women, Secretary of; Messrs. R. Crooks and Co., Liverpool; Mr. C. E. Curtice, Rickmansworth; Mr. J. F. Cantwell, Lond.; Clayton Hospital, Wakefield, Hon. Secretary of; Mr. G. A. Critchett, Lond.; Mr. B. Connell, Hardington; Cortland Wagon Co., Lond.; Mrs. E. M. Champness, Rochdale; Dr. W. H. Carruthers, Halton.

D.—Mr. F. Deighton, Cambridge; Dundee Medical Library, Assistant Librarian of; Dundee Royal Infirmary, Medical Superintendent of; Mr. A. E. Davies, Manchester; Dr. J. T. R. Davison, Buenos Ayres; Mr. W. H. Daw, Lond.; Mr. M. A. Digby, Lowestoft.

E.—Messrs. Evans and Wormull, Lond.; Messrs. Eason and Son, Dublin; Dr. C. Evans, West Norwood; Mr. H. M. Earle, Lond.; Eucalyptus, Lond.

F.—Señor J. Ferrán, Barcelona; Mr. T. R. Fraser, Brechin; Dr. H. Fraser, Harpenden; Fortiter, Lond; F. W. H., Lond.

G.—Dr. J. Gardner, Manchester; Dr. W. R. Gowers, St. Ives, Cornwall; Greer, Blofield; Messrs. R. W. Greeff and Co., Lond.

H.—Mr. M. Hime, Donegal; Dr. E. W. Haydon, Leicester; Mr. H. Hancock, Rugby; Mr. G. D. Hindley, Lond.; Mr. H. E. Haycock, Alfreton; Mrs. Heath, Southport; Mr. J. Heywood, Manchester; Huntington County Hospital, Secretary of.

I.—Messrs. Irving, Son, and Jones, Liverpool; Institute of Chemists, Lond., Registrar of.

J.—Mr. W. Jackson, Birmingham; J. D. M., Lond.

K.—Dr. L. Kidd, Lond.; Keltie Products, Ltd., Dunning; Dr. W. R. Kingdon, Sussex; Mr. R. C. B. Kerin, Lond.

L.—Mr. Henry Lee, Folkestone; Lunatic Asylums, Victoria, Australia, Inspector of; Mr. H. K. Lewis, Lond.; London Medical Mission, Superintendent of; Mr. W. W. Leigh, Treharris; Messrs. Laidlaw and Sandeman, Galashiels.

M.—Dr. A. Macfadyen, Lond.; Mr. C. Murphy, Lond.; Medical Officer of Health, Hove; Mr. E. Middlebrooke, Warboys; Dr. W. Mackie, Elgin; Mr. J. Marsden, Blackpool; Surg.-Capt. D. M. Moir, Calcutta; Mr. E. E. Mayer, Würzburg, Germany; Dr. F. Murchison, Isleworth; Manchester Children's Hospital, Pendlebury, Secretary of; Mr. R. H. Mills-Roberts, Llanberis; Manchester Royal Infirmary, Secretary of; Mason College, Birmingham, Dean of.

N.—Nurses' Coöperation, Lond., Secretary of; Mr. W. J. Naismith, St. Andrews, N.B.

O.—Dr. T. Oliver, Newcastle-on-Tyne.

P.—Dr. E. A. Peters, Lond.; Peptenzyme Co., Lond.; Pegamoid Co., Lond.; Mr. Norman Porritt, Huddersfield; Dr. F. M. Purchas, Auckland, N.Z.

Q.—Queen Margaret's College, Glasgow; Quintus, Lond.; Queen's College, Cork, Secretary of.

R.—Mr. T. L. Read, Folkestone; Rio Chemical Co., Lond.; Messrs. Robertson and Scott, Edinburgh; Mrs. J. H. E. Row, Brighton; Royal Surrey County Hospital, Guildford, Assistant Secretary of; Mr. M. O. Rogers, Hereford.

S.—Dr. S. Spicer, Lond.; Sheffield School of Medicine, Dean of; St. Mungo's College, Glasgow, Secretary of; Mr. P. H. Stirk, Tonbridge; Messrs. Street and Co., Lond.; Dr. H. Batty Shaw, Oban; Mr. R. G. Style, Lond.; Smedley's Hydropathic Establishment, Matlock, Secretary of; Sunderland Borough Asylum, Secretary of; Sell's Advertising Agency, Lond.; Mr. A. Stenhouse, Glasgow; St. Leonard's-road (151), Bromley.

T.—Mr. L. A. Tallerman, Lond.; Transvaal, Lond.; T. G., Lond.

V.—Dr. C. B. Voisey, Lond.; *Verulam Review*, Editor of.

W.—Dr. A. E. Wright, Swanage; Mr. E. Wilmshurst, Retford; Mrs. M. Wiseman, Lond.; West Ham Hospital, Secretary of; Westminster Hospital, Lond., Secretary of.

Letters, each with enclosure, are also acknowledged from—

A.—Mr. H. Astley, Portobello; A., Lond.; Anther, Lond; Abstainer, Lond.; Adelphi, Lond.; Ajax, Lond.; A. L., Lond.

B.—Mr. W. Bernard, Londonderry; Brin's Oxygen Co., Lond.; Bristol General Hospital, Secretary of; Mr. E. Baker, Birmingham; Birmingham and Midland Hospital for Skin Diseases, Secretary of; Bona fide, Lond.; Mr. A. W. Berkeley, Wrexham; Mr. N. C. Beaumont, Margate; Messrs. Bishop and Sons, Lond.; Col. Badgley, Exmouth; Dr. T. S. Brodie, Houston; Benedict, Lond.; Messrs. Burroughs, Wellcome, and Co., Lond.; B., West Malling; Mr. M. Buchner, Lond.

C.—Mr. W. Crooke, Egremont; Mrs. Chapman, Lond.; Cicero, Lond.; Mr. J. Campbell, Small Isles, Elgg; Mr. J. C. Cheeseman, Pearston, Cape Colony; Dr. Crabb, Lond; Dr. T. Colvin, Glasgow; Mr. J. N. Cregeen, Liverpool; Messrs. T. Christy and Co., Lond.

D.—Dunelm, Lond.; Dorset, Lond.; Doctor, York; Dundee Royal Infirmary, Treasurer of.

E.—Mr. J. A. Eyton-Jones, Wrexham; E., Middlesboro'; Dr. C. Elgood, Windsor; Excelsior, Lond.; Dr. O. Eaton, Exmouth.

F.—Dr. R. Furdunjee, Hyderabad, India; F. W. T., New Cross.

G.—Gonion, Lond.; G. Mc H., Lond.; G. R. D., Lond.

H.—Mr. A. Humphrey, Burton-on-Trent; Mr. A. S. Hanson, Titchfield; Mr. T. G. Horder, Cardiff; Mr. E. Huxley, Lond.; Mr. M. C. Hime, Buncrana.

I.—Messrs. Idris and Co., Lond.

J.—J. W., Lond.

K.—Dr. R. L. Knaggs, Leeds; Mr. A. C. Kemble, Winchfield.

L.—Mr. N. Longmore, Woolston; London Temperance Hospital, Secretary of.

Presidential Address,

Delivered at the Annual Meeting of the British Association for the Advancement of Science at Toronto, 1897,

BY SIR JOHN EVANS, K.C.B., D.C.L., LL.D., Sc.D.,
CORRESPONDANT DE L'INSTITUT DE FRANCE, ETC.

GENTLEMEN,—Once more has the Dominion of Canada invited the British Association for the Advancement of Science to hold one of the annual meetings of its members within the Canadian territory, and for a second time has the association had the honour and pleasure of accepting the proferred hospitality. In doing so the association has felt that if by any possibility the scientific welfare of a locality is promoted by its being the scene of such a meeting, the claims should be fully recognised of those who, though not dwelling in the British Isles, are still inhabitants of that Greater Britain, whose prosperity is so intimately connected with the fortunes of the mother country. Here, especially, as loyal subjects of one beloved Sovereign, the sixtieth year of whose beneficent reign has just been celebrated with equal rejoicing in all parts of her empire, as speaking the same tongue, and as in most instances connected by the ties of one common parentage, we are bound together in all that can promote our common interests. There is, in all probability, nothing that will tend more to advance those interests than the diffusion of science in all parts of the British Empire, and it is towards this end that the aspirations of the British Association are ever directed, even if in many instances the aim may not be attained.

We are, as already mentioned, indebted to Canada for previous hospitality, but we must also remember that, since the time when we last assembled on this side of the Atlantic, the Dominion has provided the association with a President, Sir William Dawson, whose name is alike well known in Britain and America, and whose reputation is indeed world-wide. We rejoice that we have still among us the pioneer of American geology, who among other discoveries first made us acquainted with the "Air Breathers of the Coal," the terrestrial or more properly arboreal saurians of the New Brunswick and Nova Scotia coal-measures.

On our last visit to Canada, in 1884, our place of assembly was Montreal, a city which is justly proud of her McGill University; to-day we meet within the buildings of another of the universities of this vast Dominion, and in a city the absolute fitness of which for such a purpose must have been foreseen by the native Indian tribes when they gave to a small aggregation of huts upon this spot the name of Toronto —"the place of meetings." Our gathering this year presents a feature of entire novelty and extreme interest, inasmuch as the sister association of the United States of America—still mourning the loss of her illustrious President, Professor Cope—and some other learned societies have made special arrangements to allow of their members coming here to join us. I need hardly say how welcome their presence is, or how gladly we look forward to their taking part in our discussions and aiding us by interchange of thought. To such a meeting the term "international" seems almost misapplied. It may rather be described as a family gathering, in which our relatives more or less distant in blood, but still intimately connected with us by language, literature, and habits of thought, have spontaneously arranged to take part. The domain of science is no doubt one in which the various nations of the civilised world meet upon equal terms, and for which no other passport is required than some evidence of having striven towards the advancement of natural knowledge. Here, on the frontier between the two great English-speaking nations of the world, who is there that does not inwardly feel that anything which conduces to an intimacy between the representatives of two countries, both of them actively engaged in the pursuit of science, may also, through such an intimacy, re-act on the affairs of daily life and aid in preserving those cordial relations that have now for so many years existed between the great American Republic and the British Islands, with which her early foundations are indissolubly connected? The present year has witnessed an interchange of courtesies which has excited the warmest feelings of approbation on both sides of the Atlantic—I mean the return to its proper custodians of one of the most interesting of the relics of the Pilgrim Fathers, the log of the *Mayflower*. May this return, trifling in itself, be of happy augury as testifying to the feelings of mutual regard and esteem which animate the hearts both of the donors and of the recipients.

At our meeting in Montreal the President was an investigator who had already attained to a foremost place in the domains of physics and mathematics, Lord Rayleigh. In his address he dealt mainly with topics such as light, heat, sound, and electricity, on which he is one of our principal authorities. His name and that of his fellow-worker, Professor Ramsay, are now and will in all future ages be associated with the discovery of the new element, argon. Of the ingenious methods by which that discovery was made, and the existence of argon established, this is not the place to speak. One can only hope that the element will not always continue to justify its name by its inertness. The claims of such a leader in physical science as Lord Rayleigh to occupy the presidential chair are self-evident, but possibly those of his successor on this side of the Atlantic are not so immediately apparent. I cannot for a moment pretend to place myself on the same purely scientific level as my distinguished friend and for many years colleague, Lord Rayleigh, and my claims, such as they are, seem to me to rest on entirely different grounds. Whatever little I may have indirectly been able to do in assisting to promote the advancement of science, my principal efforts have now for many years been directed towards attempting to forge those links in the history of the world, and especially of humanity, that connect the past with the present, and towards tracing that course of evolution which plays as important a part in the physical and moral development of man as it does in that of the animal and vegetable creation. It appears to me, therefore, that my election to this important post may, in the main, be regarded as a recognition by this association of the value of archæology as a science. Leaving all personal considerations out of question, I gladly hail this recognition, which is, indeed, in full accordance with the attitude already for many years adopted by the association towards anthropology, one of the most important branches or true archæology.

It is no doubt hard to define the exact limits which are to be assigned to archæology as a science and archæology as a branch of history and *belles lettres*. A distinction is frequently drawn between science on the one hand and knowledge or learning on the other; but translate the terms into Latin and the distinction at once disappears. In illustration of this I need only cite Bacon's great work on the "Advancement of Learning," which was, with his own aid, translated into Latin under the title "*De Augmentis Scientiarum*." It must, however, be acknowledged that a distinction does exist between archæology proper and what, for want of a better word, may be termed antiquarianism. It may be interesting to know the internal arrangements of a dominican convent in the middle ages; to distinguish between the different mouldings characteristic of the principal styles of Gothic architecture; to determine whether an English coin bearing the name of Henry was struck under Henry II., Richard, John, or Henry III; or to decide whether some given edifice was erected in Roman, Saxon, or Norman times. But the power to do this, though involving no small degree of detailed knowledge and some acquaintance with scientific methods, can hardly entitle its possessors to be enrolled among the votaries of science. A familiarity with all the details of Greek and Roman mythology and culture must be regarded as a literary rather than a scientific qualification; and yet when among the records of classical times we come upon traces of manners and customs which have survived for generations, and which seem to throw some rays of light upon the dim past, when history and writing were unknown, we are, I think, approaching the boundaries of scientific archæology.

Every reader of Virgil knows that the Greeks were not merely orators, but that with a pair of compasses they could describe the movements of the heavens and fix the rising of the stars; but when by modern astronomy we can determine the heliacal rising of some well-known star, with which the worship in some given ancient temple is known to have been connected, and can fix its position on the horizon at some particular spot, say, three thousand years ago, and then find that the axis of the temple is directed exactly towards

Digitized by Google

that spot, we have some trustworthy scientific evidence that the temple in question must have been erected at a date approximately 1100 years B C. If on or close to the same site we find that more than one temple was erected, each having a different orientation, these variations, following, as they may fairly be presumed to do, the changing position of the rising of the dominant star, will also afford a guide as to the chronological order of the different foundations. The researches of Mr. Penrose seem to show that in certain Greek temples, of which the date of foundation is known from history, the actual orientation corresponds with that theoretically deduced from astronomical data. Sir J. Norman Lockyer has shown that what holds good for Greek temples applies to many of far earlier date in Egypt, though up to the present time hardly a sufficient number of accurate observations have been made to justify us in foreseeing all the instructive results that may be expected to arise from astronomy coming to the aid of archæology. The intimate connexion of archæology with other sciences is in no case so evident as with respect to geology, for when considering subjects such as those I shall presently discuss it is almost impossible to say where the one science ends and the other begins.

By the application of geological methods many archæological questions relating even to subjects on the borders of the historical period have been satisfactorily solved. A careful examination of the limits of the area over which its smaller coins are found has led to the position of many an ancient Greek city being accurately ascertained; while in England it has only been by treating the coins of the Ancient Britons, belonging to a period before the Roman occupation, as if they were actual fossils that the territories under the dominion of the various kings and princes who struck them have been approximately determined. In arranging the chronological sequence of these coins, the evolution of their types—a process almost as remarkable, and certainly as well-defined, as any to be found in nature—has served as an efficient guide. I may venture to add that the results obtained from the study of the morphology of this series of coins were published ten years before the appearance of Darwin's great work on the "Origin of Species." When we come to the consideration of the relics of the early iron and bronze ages the aid of chemistry has of necessity to be invoked. By its means we are able to determine whether the iron of a tool or weapon is of meteoritic or volcanic origin, or has been reduced from iron-ore, in which case considerable knowledge of metallurgy would be involved on the part of those who made it. With bronze antiquities the nature and extent of the alloys combined with the copper may throw light not only on their chronological position, but on the sources whence the copper, tin, and other metals of which they consist were originally derived. I am not aware of there being sufficient differences in the analyses of the native copper from different localities in the region in which we are assembled for Canadian archæologists to fix the sources from which the metal was obtained which was used in the manufacture of the ancient tools and weapons of copper that are occasionally discovered in this part of the globe. Like chemistry, mineralogy, and petrology may be called to the assistance of archæology in determining the nature and source of the rocks of which ancient stone implements are made; and, thanks to researches of the followers of those sciences, the old view that all such implements formed of jade and found in Europe must of necessity have been fashioned from material imported from Asia can no longer be maintained. In one respect the archæologist differs in opinion from the mineralogist—namely, as to the propriety of chipping off fragments from perfect and highly finished specimens for the purpose of submitting them to microscopic examination.

I have hitherto been speaking of the aid that other sciences can afford to archæology when dealing with questions that come almost, if not quite, within the fringe of history, and belong to times when the surface of our earth presented much the same configuration as regards the distribution of land and water and hill and valley as it does at present, and when in all probability the climate was much the same as it now is. When, however, we come to discuss that remote age in which we find the earliest traces that are at present known of man's appearance upon earth the age of geology and palæontology becomes absolutely imperative. The changes in the surface configuration and in the extent of the land, especially in a country like Britain, as well as the modifications of the fauna and flora since those days, have been such that the archæologist pure and simple is incompetent to deal with them, and he must either himself undertake the study of these other sciences or call experts in them to his assistance. The evidence that man had already appeared upon the earth is afforded by stone implements wrought by his hands, and it falls strictly within the province of the archæologist to judge whether given specimens were so wrought or not; it rests with the geologist to determine their stratigraphical or chronological position, while the palæontologist can pronounce upon the age and character of the associated fauna and flora. If left to himself the archæologist seems too prone to build up theories founded upon form alone, irrespective of geological conditions. The geologist, unaccustomed to archæological details, may readily fail to see the difference between the results of the operations of Nature and those of Art, and may be liable to trace the effects of man's handiwork in the chipping, bruising, and wearing which in all ages result from natural forces; but the united labours of the two, checked by those of the palæontologist, cannot do otherwise than lead towards sound conclusions.

It will perhaps be expected of me that I should on the present occasion bring under review the state of our present knowledge with regard to the antiquity of man; and probably no fitter place could be found for the discussion of such a topic than the adopted home of my venerated friend, the late Sir Daniel Wilson, who first introduced the word "prehistoric" into the English language. Some among us may be able to call to mind the excitement, not only among men of science, but among the general public, when, in 1859, the discoveries of M. Boucher de Perthes and Dr. Rigollot in the gravels of the valley of the Somme, at Abbeville and Amiens, were confirmed by the investigations of the late Sir Joseph Prestwich, myself, and others, and the co-existence of man with the extinct animals of the quaternary fauna, such as the mammoth and woolly-haired rhinoceros, was first virtually established. It was at the same time pointed out that these relics belonged to a far earlier date than the ordinary stone weapons found upon the surface, which usually showed signs of grinding or polishing, and that, in fact, there were two stone ages in Britain. To these the terms "neolithic" and "palæolithic" were subsequently applied by Sir John Lubbock. The excitement was not less when, at the meeting of this association at Aberdeen in the autumn of that year, Sir Charles Lyell, in the presence of the Prince Consort, called attention to the discoveries in the valley of the Somme, the site of which he had himself visited, and to the vast lapse of time indicated by the position of the implements in drift deposits a hundred feet above the existing river. The conclusions forced upon those who examined the facts on the spot did not receive immediate acceptance by all who were interested in geology and archæology, and fierce were the controversies on the subject that were carried on both in the newspapers and before various learned societies. It is at the same time instructive and amusing to look back on the discussions of those days. While one class of objectors accounted for the configuration of the flint implements from the gravels by some unknown chemical agency, by the violent and continued gyratory action of water, by fracture resulting from pressure, by rapid cooling when hot or by rapid heating when cold, or even regarded them as aberrant forms of fossil fishes, there were others who, when compelled to acknowledge that the implements were the work of men's hands, attempted to impugn and set aside the evidence as to the circumstances under which they had been discovered. In doing this they adopted the view that the worked flints had either been introduced into the containing beds at a comparatively recent date, or if they actually formed constituent parts of the gravel then that this was a mere modern alluvium resulting from floods at no very remote period. In the course of a few years the main stream of scientific thought left this controversy behind, though a tendency to cut down the lapse of time necessary for all the changes that have taken place in the configuration of the surface of the earth and in the character of its occupants since the time of the palæolithic gravels still survives in the inmost recesses of the hearts of not a few observers.

In his address to this association at the Bath meeting of 1864 Sir Charles Lyell struck so true a note that I am tempted to reproduce the paragraph to which I refer: "When speculations on the long series of events which occurred in the glacial and post-glacial periods are indulged in, the imagination is apt to take alarm at the immensity of the time required to interpret the monuments of these ages,

Digitized by Google

all referable to the era of existing species. In order to abridge the number of centuries which would otherwise be indispensable, a disposition is shown by many to magnify the rate of change in prehistoric times by investing the causes which have modified the animate and inanimate world with extraordinary and excessive energy. It is related of a great Irish orator of our day that when he was about to contribute somewhat parsimoniously towards a public charity he was persuaded by a friend to make a more liberal donation. In doing so he apologised for his first apparent want of generosity by saying that his early life had been a constant struggle with scanty means, and that 'they who are born to affluence cannot easily imagine how long a time it takes to get the chill of poverty out of one's bones.' In like manner we of the living generation, when called upon to make grants of thousands of centuries in order to explain the events of what is called the modern period, shrink naturally at first from making what seems so lavish an expenditure of past time. Throughout our early education we have been accustomed to such strict economy in all that relates to the chronology of the earth and its inhabitants in remote ages, so fettered have we been by old traditional beliefs, that even when our reason is convinced and we are persuaded that we ought to make more liberal grants of time to the geologist, we feel how hard it is to get the chill of poverty out of our bones." Many, however, have at the present day got over this feeling, and of late years the general tendency of those engaged upon the question of the antiquity of the human race has been in the direction of seeking for evidence by which the existence of man upon the earth could be carried back to a date earlier than that of the quaternary gravels. There is little doubt that such evidence will eventually be forthcoming, but, judging from all probability, it is not in Northern Europe that the cradle of the human race will eventually be discovered, but in some part of the world more favoured by a tropical climate, where abundant means of subsistence could be procured, and where the necessity for warm clothing did not exist. Before entering into speculations on this subject, or attempting to lay down the limits within which we may safely accept recent discoveries as firmly established, it will be well to glance at some of the cases in which implements are stated to have been found under circumstances which raise a presumption of the existence of man in pre-glacial, pliocene, or even miocene times.

Flint implements of ordinary palæolithic type have, for instance, been recorded as found in the eastern counties of England in beds beneath the chalky boulder clay; but on careful examination the geological evidence has not to my mind proved satisfactory, nor has it, I believe, been generally accepted. Moreover, the archæological difficulty that man, at two such remote epochs as the pre-glacial and the post-glacial, even if the term "glacial" be limited to the chalky boulder clay, should have manufactured implements so identical in character that they cannot be distinguished apart, seems to have been entirely ignored. Within the last few months we have had the report of worked flints having been discovered in the late pliocene forest bed of Norfolk, but in that instance the signs of human workmanship upon the flints are by no means apparent to all observers. But such an antiquity as that of the forest bed is as nothing when compared with that which would be implied by the discoveries of the work of men's hands in the pliocene and miocene beds of England, France, Italy, and Portugal, which have been accepted by some geologists. There is one feature in these cases which has hardly received due attention, and that is the isolated character of the reputed discoveries. Had man, for instance, been present in Britain during the crag period, it would be strange indeed if the sole traces of his existence that he left were a perforated tooth of a large shark, the sawn rib of a manatee, and a beaming full face carved on the shell of a pectunculus!

In an address to the Anthropological Section at the Leeds meeting of this association in 1890 I dealt somewhat fully with these supposed discoveries of the remains of human art in beds of tertiary date; and I need not here go further into the question. Suffice it to say that I see no reason why the verdict of "not proven" at which I then arrived should be reversed. In the case of a more recent discovery in Upper Burma in beds at first pronounced to be upper miocene, but subsequently "definitely ascertained to be pliocene," some of the flints are of purely natural and not artificial origin, so that two questions arise: first, Were the fossil remains associated with the worked flints or with those of natural forms? and second, Were they actually found in the bed to which they have been assigned, or did they merely lie together on the surface? Even the *Pithecanthropus erectus* of Dr. Eugène Dubois from Java meets with some incredulous objectors from both the physiological and the geological sides. From the point of view of the latter the difficulty lies in determining the exact age of what are apparently alluvial beds in the bottom of a river valley.

When we return to palæolithic man it is satisfactory to feel that we are treading on comparatively secure ground, and that the discoveries of the last forty years in Britain alone enable us to a great extent to reconstitute his history. We may not know the exact geological period when first he settled in the British area, but we have good evidence that he occupied it at a time when the configuration of the surface was entirely different from what it is at present, when the river valleys had not been cut down to anything like their existing depth, when the fauna of the country was of a totally different character from that of the present day, when the extension of the southern part of the island seaward was in places such that the land was continuous with that of the continent, and when in all probability a far more rainy climate prevailed. We have proofs of the occupation of the country by man during the long lapse of time that was necessary for the excavation of the river valleys. We have found the old floors on which his habitations were fixed, we have been able to trace him at work on the manufacture of flint instruments, and by building up the one upon the other the flakes struck off by the primæval workman in those remote times we have been able to reconstruct the blocks of flint which served as his material. That the duration of the palæolithic period must have extented over an almost incredible length of time is sufficiently proved by the fact that valleys, some miles in width and of a depth of from 100 to 150 ft., have been eroded since the deposit of the earliest implement-bearing beds. Nor is the apparent duration of this period diminished by the consideration that the floods which hollowed out the valleys were not in all probability of such frequent occurrence as to teach palæolithic man by experience the danger of settling too near to the streams, for had he kept to the higher slopes of the valley there would have been but little chance of his implements having so constantly formed constituent parts of the gravels deposited by the floods.

The examination of British cave-deposits affords corroborative evidence of this extended duration of the palæolithic period. In Kent's Cavern at Torquay, for instance, we find in the lowest deposit, the breccia below the red cave-earth, implements of flint and chert corresponding in all respects with those of the high level and most ancient river gravels. In the cave-earth these are scarcer, though implements occur which also have their analogues in the river deposits; but, what is more remarkable, harpoons of reindeer's horn and needles of bone are present, identical in form and character with those of the caverns of the reindeer period in the South of France, and suggestive of some bond of union or identity of descent between the early troglodytes, whose habitations were geographically so widely separated the one from the other.

In a cavern at Creswell Crags, on the confines of Derbyshire and Nottinghamshire, a bone has, moreover, been found engraved with a representation of parts of a horse in precisely the same style as the engraved bones of the French caves. It is uncertain whether any of the river-drift specimens belong to so late a date as these artistic cavern remains; but the greatly superior antiquity of even these to any neolithic relics is testified by the thick layer of stalagmite which had been deposited in Kent's Cavern before its occupation by men of the neolithic and bronze periods. Towards the close of the period covered by the human occupation of the French caves there seems to have been a dwindling in the number of the larger animals constituting the quaternary fauna, whereas their remains are present in abundance in the lower and therefore more recent of the valley gravels. This circumstance may afford an argument in favour of regarding the period represented by the later French caves as a continuation of that during which the old river gravels were deposited, and yet the great change in the fauna that has taken place since the latest of the cave deposits included in the palæolithic period is indicative of an immense lapse of time. How much greater must have been the time required for the more

Digitized by Google

conspicuous change between the old quaternary fauna of the river gravels and that characteristic of the neolithic period. As has been pointed out by Professor Boyd Dawkins, only thirty-one out of the forty-eight well-ascertained species living in the post-glacial or river-drift period survived into prehistoric or neolithic times. We have not, indeed, any means at command for estimating the number of centuries which such an important change indicates; but when we remember that the date of the commencement of the neolithic or surface stone period is still shrouded in the mist of a dim antiquity, and that prior to that commencement the river-drift period had long come to an end; and when we further take into account the almost inconceivable ages that even under the most favourable conditions the excavation of wide and deep valleys by river action implies, the remoteness of the date at which the palæolithic period had its beginning almost transcends our powers of imagination. We find distinct traces of river action from 100 to 200 feet above the level of existing streams and rivers, and sometimes at a great distance from them; we observe old fresh-water deposits on the slopes of the valleys several miles in width; we find that long and lofty escarpments of rock have receded unknown distances since their summits were first occupied by palæolithic man; we see that the whole side of a wide river valley has been carried away by an invasion of the sea, which attacked and removed a barrier of chalk cliffs from 400 to 600 feet in height; we find that what was formerly an inland river has been widened out into an arm of the sea, now the highway of our fleets, and that gravels which were originally deposited in the bed of some ancient river now cap isolated and lofty hills.

And yet, remote as the date of the first known occupation of Britain by man may be, it belongs to what, geologically speaking, must be regarded as a quite recent period, for we are now in a position to fix with some degree of accuracy its place on the geological scale. Thanks to investigations ably carried out at Hoxne, in Suffolk, and at Hitchin, in Hertfordshire, by Mr. Clement Reid, under the auspices of this association and of the Royal Society, we know that the implement-bearing beds at those places undoubtedly belong to a time subsequent to the deposit of the great chalky boulder clay of the eastern counties of England. It is, of course, self-evident that this vast deposit, in whatever manner it may have been formed, could not for centuries after its deposition was complete have presented a surface inhabitable by man. Moreover, at a distance but little farther north beds exist which also, though at a somewhat later date, were apparently formed under glacial conditions. At Hoxne the interval between the deposit of the boulder clay and of the implement-bearing beds is distinctly proved to have witnessed at least two noteworthy changes in climate. The beds immediately reposing on the clay are characterised by the presence of alder in abundance, of hazel and yew, as well as by that of numerous flowering plants indicative of a temperate climate very different from that under which the boulder clay itself was formed. Above these beds, characterised by temperate plants, comes a thick and more recent series of strata, in which leaves of the dwarf Arctic willow and birch abound, and which were in all probability deposited under conditions like those of the cold regions of Siberia and North America. At a higher level and of more recent date than these—from which they are entirely distinct—are the beds containing palæolithic implements, formed in all probability under conditions not essentially different from those of the present day. However this may be, we have now conclusive evidence that the palæolithic implements are, in the eastern counties of England, of a date long posterior to that of the great chalky boulder clay.

It may be said, and said truly, that the implements at Hoxne cannot be shown to belong to the beginning rather than to some later stage of the palæolithic period. The changes, however, that have taken place at Hoxne in the surface configuration of the country prove that the beds containing the implements cannot belong to the close of that period. It must, moreover, be remembered that in what are probably the earliest of the palæolithic deposits of the eastern counties, those at the highest level, near Brandon in Norfolk, where the gravels contain the largest proportion of pebbles derived from glacial beds, some of the implements themselves have been manufactured from materials not native to the spot, but brought from a distance, and derived in all probability either from the boulder clay or from some of the beds associated with it. We must, however, take a wider view of the whole question, for it must not for a moment be supposed that there are the slightest grounds for believing that the civilisation, such as it was, of the palæolithic period originated in the British Isles. We find in other countries implements so identical in form and character with British specimens that they might have been manufactured by the same hands. These occur over large areas in France under similar conditions to those that prevail in England. The same forms have been discovered in the ancient river gravels of Italy, Spain, and Portugal. Some few have been recorded from the north of Africa, and analogous types occur in considerable numbers in the south of that continent. On the banks of the Nile, many hundreds of feet above its present level, implements of the European types have been discovered; while in Somaliland, in an ancient river valley at a great elevation above the sea, Mr. Seton-Karr has collected a large number of implements formed of flint and quartzite, which, judging from their form and character, might have been dug out of the drift deposits of the Somme or the Seine, the Thames or the ancient Solent. In the valley of the Euphrates implements of the same kind have also been found, and again farther east in the lateritic deposits of Southern India they have been obtained in considerable numbers. It is not a little remarkable, and is at the same time highly suggestive, that a form of implement almost peculiar to Madras reappears among implements from the very ancient gravels of the Manzanares at Madrid. In the case of the African discoveries we have as yet no definite palæontological evidence by which to fix their antiquity, but in the Narbadá Valley of Western India palæolithic implements of quartzite seem to be associated with a local fauna of pleistocene age, comprising, like that of Europe, the elephant, hippopotamus, ox, and other mammals of species now extinct. A correlation of the two faunas with a view of ascertaining their chronological relations is beset with many difficulties, but there seems reason for accepting this Indian pleistocene fauna as in some degree more ancient than the European.

Is this not a case in which the imagination may be fairly invoked in aid of science? May we not from these data attempt in some degree to build up and reconstruct the early history of the human family? There, in Eastern Asia, in a tropical climate, with the means of subsistence readily at hand, may we not picture to ourselves our earliest ancestors gradually developing from a lowly origin, acquiring a taste for hunting, if not indeed being driven to protect themselves from the beasts around them, and evolving the more complicated forms of tools or weapons from the simpler flakes which had previously served them as knives? May we not imagine that when once the stage of civilisation denoted by these palæolithic implements had been reached the game for the hunter became scarcer and that his life in consequence assumed a more nomad character? Then, and possibly not till then, may a series of migrations to "fresh woods and pastures new" not unnaturally have ensued, and these following the usual course of "westward towards the setting sun" might eventually lead to a palæolithic population finding its way to the extreme borders of Western Europe, where we find such numerous traces of its presence. How long a term of years may be involved in such a migration it is impossible to say, but that such a migration took place the phenomena seem to justify us in believing. It can hardly be supposed that the process that I have shadowed forth was reversed, and that man, having originated in north-western Europe, in a cold climate where clothing was necessary and food scarce, subsequently migrated eastward to India and southward to the Cape of Good Hope? As yet our records of discoveries in India and Eastern Asia are but scanty; but it is there that the traces of the cradle of the human race are, in my opinion, to be sought, and possibly future discoveries may place upon a more solid foundation the visionary structure that I have ventured to erect.

It may be thought that my hypothesis does not do justice to what Sir Thomas Browne has so happily termed "that great antiquity, America." I am, however, not here immediately concerned with the important neolithic remains of all kinds with which this great continent abounds. I am now confining myself to the question of palæolithic man and his origin, and in considering it I am not unmindful of the Trenton implements, though I must content myself by saying that the "turtle-back" form is essentially different from the majority of those on the wide dissemination of which I have been speculating, and, moreover, as many here

Digitized by Google

present are aware, the circumstances of the finding of these American implements are still under careful discussion. Leaving them out of the question for the present, it may be thought worth while to carry our speculations rather further, and to consider the relations in time between the palæolithic and the neolithic periods. We have seen that the stage in human civilisation denoted by the use of the ordinary forms of palæolithic implements must have extended over a vast period of time if we have to allow for the migration of the primæval hunters from their original home, wherever it may have been in Asia or Africa, to the west of Europe, including Britain. We have seen that during this migration the forms of the weapons and tools made from silicious stones had become, as it were, stereotyped, and, further, that during the subsequent extended period implied by the erosion of the valleys the modifications in the form of the implements and the changes in the fauna associated with the men who used them were but slight. At the close of the period during which the valleys were being eroded comes that represented by the latest occupation of the caves by palæolithic man when both in Britain and in the south of France the reindeer was abundant; but among the stone weapons and implements of that long troglodytic phase of man's history not a single example with the edge sharpened by grinding has as yet been found. All that can safely be said is that the larger implements as well as the larger mammals had become scarcer, that greater power in chipping flint had been attained, that the arts of the engraver and the sculptor had considerably developed, and that the use of the bow had probably been discovered. Directly we encounter the relics of the neolithic period, often, in the case of the caves lately mentioned, separated from the earlier remains by a thick layer of underlying stalagmite, we find flint hatchets polished at the edge and on the surface, cutting at the broad and not at the narrow end, and other forms of implements associated with a fauna in all essential respects identical with that of the present day.

Were the makers of these polished weapons the direct descendants of palæolithic ancestors whose occupation of the country was continuous from the days of the old river gravels? or had these long since died out, so that after Western Europe had for ages remained uninhabited it was re-peopled in neolithic times by the immigration of some new race of men? Was there, in fact, a "great gulf fixed" between the two occupations? or was there in Europe a gradual transition from the one stage of culture to the other? It has been said that "what song the syrens sang, or what name Achilles assumed when he hid himself among women, though puzzling questions, are not beyond all conjecture"; and though the questions now proposed may come under the same category, and must await the discovery of many more essential facts before they receive definite and satisfactory answers, we may, I think, throw some light upon them if we venture to take a few steps upon the seductive if insecure paths of conjecture. So far as I know we have as yet no trustworthy evidence of any transition from the one age to the other, and the gulf between them remains practically unbridged. We can, indeed, hardly name the part of the world in which to seek for the cradle of neolithic civilisation, though we know that traces of what appear to have been a stone-using people have been discovered in Egypt, and that what must be among the latest of the relics of their industry have been assigned to a date some 3500 to 4000 years before our era. The men of that time had attained to the highest degree of skill in working flint that has ever been reached. Their beautifully made knives and spearheads seem indicative of a culminating point reached after long ages of experience; but whence these artists in flint came or who they were is at present absolutely unknown, and their handiworks afford no clue to help us in tracing their origin. Taking a wider survey, we may say that, generally speaking, not only the fauna but the surface configuration of the country were, in Western Europe at all events, much the same at the commencement of the neolithic period as they are at the present day. We have, too, no geological indications to aid us in forming any chronological scale.

The occupation of some of the caves in the south of France seems to have been carried on after the erosion of the neighbouring river valleys had ceased, and so far as our knowledge goes these caves offer evidence of being the latest in time of those occupied by man during the palæolithic period. It seems barely possible that though in the north of Europe there are no distinct signs of such late occupation, yet that in the south man may have lived on, though in diminished numbers; and that in some of the caves, such, for instance, as those in the neighbourhood of Mentone, there may be traces of his existence during the transitional period that connects the palæolithic and neolithic ages. If this were really the case we might expect to find some traces of a dissemination of neolithic culture from a North Italian centre, but I much doubt whether any such traces actually exist. If it had been in that part of the world that the transition took place, how are we to account for the abundance of polished stone hatchets found in Central India? Did neolithic man return eastward by the same route as that by which in remote ages his palæolithic predecessor had migrated westward? Would it not be in defiance of all probability to answer such a question in the affirmative? We have, it must be confessed, nothing of a substantial character to guide us in these speculations; but, pending the advent of evidence to the contrary, we may, I think, provisionally adopt the view that owing to failure of food, climatal changes, or other causes, the occupation of Western Europe by palæolithic man absolutely ceased, and that it was not until after an interval of long duration that Europe was re-peopled by a race of men immigrating from some other part of the globe where the human race had survived, and in course of ages had developed a higher stage of culture than that of palæolithic man.

I have been carried away by the liberty allowed for conjecture into the regions of pure imagination, and must now return to the realms of fact, and one fact on which I desire for a short time to insist is that of the existence at the present day, in close juxtaposition with our own civilisation, of races of men who—at all events but a few generations ago—lived under much the same conditions as did our own neolithic predecessors in Europe. The manners and customs of these primitive tribes and peoples are changing day by day, their languages are becoming obsolete, their myths and traditions are dying out, their ancient processes of manufacture are falling into oblivion, and their numbers are rapidly diminishing, so that it seems inevitable that ere long many of these interesting populations will become absolutely extinct. The admirable Bureau of Ethnology instituted by our neighbours in the United States of America has done much towards preserving a knowledge of the various native races in this vast continent; and here in Canada the annual Archæological Reports presented to the Minister of Education are rendering good service in the same cause. Moreover, the committee of this association appointed to investigate the physical characters, languages, and industrial and social conditions of the north-western tribes of the Dominion of Canada is about to present its twelfth and final report, which, in conjunction with those already presented, will do much towards preserving a knowledge of the habits and languages of those tribes. It is sad to think that Mr. Horatio Hale, whose comprehensive grasp of the bearings of ethnological questions, and whose unremitting labours have so materially conduced to the success of the committee, should be no longer among us. Although this report is said to be final, it is to be hoped that the committee may be able to indicate lines upon which future work in the direction of ethnological and archæological research may be profitably carried on in this part of Her Majesty's dominions. It is, however, lamentable to notice how little is being or has been officially done towards preserving a full record of the habits, beliefs, arts, myths, languages, and physical characteristics of the countless other tribes and nations more or less uncivilised which are comprised within the limits of the British Empire. At the meeting of this association held last year at Liverpool it was resolved by the general committee "that it is of urgent importance to impress upon the Government the necessity of establishing a Bureau of Ethnology for Greater Britain, which, by collecting information with regard to the native races within and on the borders of the empire, will prove of immense value to science and to the Government itself." It has been suggested that such a bureau might with the greatest advantage and with the least outlay and permanent expense be connected either with the British Museum or with the Imperial Institute, and the project has already been submitted for the consideration of the trustees of the former establishment The existence of an almost unrivalled ethnological collection in the museum, and the presence there of officers already well versed in ethnological research, seem to afford an argument in

Digitized by Google

favour of the proposed bureau being connected with it. On the other hand, the Imperial Institute was founded with an especial view to its being a centre around which every interest connected with the dependencies of the Empire might gather for information and support. The establishment within the last twelve months of a scientific department within the Institute, with well-appointed laboratories and a highly trained staff, shows how ready are those concerned in its management to undertake any duties that may conduce to the welfare of the outlying parts of the British Empire—a fact of which I believe that Canada is fully aware. The Institute is therefore likely to develop, so far as its scientific department is concerned, into a bureau of advice in all matters scientific and technical, and certainly a Bureau of Ethnology such as that suggested would not be out of place within its walls. Wherever such an institution is to be established, the question of its existence must of necessity rest with Her Majesty's Government and Treasury, inasmuch as without funds, however moderate, the undertaking cannot be carried on. I trust that in considering the question it will always be borne in mind that in the relations between civilised and uncivilised nations and races it is of the first importance that the prejudices, and especially the religious or semi-religious and caste prejudices of the latter should be thoroughly well known to the former. If but a single "little war" could be avoided in consequence of the knowledge acquired and stored up by the Bureau of Ethnology preventing such a misunderstanding as might culminate in warfare, the cost of such an institution would quickly be saved.

I fear that it will be thought that I have dwelt too long on primæval man and his modern representatives, and that I should have taken this opportunity to discuss some more general subject, such as the advances made in the various departments of science since last this association met in Canada. Such a subject would no doubt have afforded an infinity of interesting topics on which to dilate. Spectrum analysis, the origin and nature of celestial bodies, photography, the connexion between heat, light, and electricity, the practical applications of the latter, terrestrial magnetism, the liquefaction and solidification of gases, the behaviour of elements and compounds under the influence of extreme cold, the nature and uses of the Roentgen rays, the advances in bacteriology and in prophylactic medicine, might all have been passed under review, and to many of my audience would have seemed to possess greater claims to attention than the subject that I have chosen. It must, however, be borne in mind that most, if not indeed all, of these topics will be discussed by more competent authorities in the various sections of the association by means of the presidential addresses or otherwise. Nor must it be forgotten that I occupy this position as a representative of archæology, and am therefore justified in bringing before you a subject in which every member of every race of mankind ought to be interested—the antiquity of the human family and the scenes of its infancy.

Others will direct our thoughts in other directions, but the farther we proceed the more clearly shall we realise the connexion and interdependence of all departments of science. Year after year, as meetings of this association take place, we may also foresee that "many shall run to and fro and knowledge shall be increased." Year after year advances will be made in science and in reading that Book of Nature that lies ever open before our eyes; successive stones will be brought for building up that temple of knowledge of which our fathers and we have laboured to lay the foundations. May we not well exclaim with old Robert Recorde: "Oh woorthy temple of Goddes magnificence: Oh throne of glorye and seate of the lorde: thy substance most pure what tonge can describe? thy signes are so wonderous, surmountinge mannes witte, the effects of thy motions so diuers in kinde: so harde for to searche, and worse for to fynde—Thy woorkes are all wonderous, thy cunning unknowen: yet seedes of all knowledge in that booke are sowen—And yet in that boke who rightly can reade, to all secrete knowledge it will him straighte leade."[1]

[1] Preface to Robert Recorde's Castle of Knowledge, 1556.

VACCINATION GRANT.—Dr. John Hamilton, of Burton-on-Trent, has obtained the Government grant for efficient vaccination in the Gresley District, Burton-on-Trent Union, for the tenth time.

An Address

ON THE

RELATIONSHIP OF PHYSIOLOGY, PHARMACOLOGY, PATHOLOGY, AND PRACTICAL MEDICINE.

Delivered at the International Medical Congress at Moscow on Aug. 7th (19th), 1897,

BY T. LAUDER BRUNTON, M.D., D.Sc. EDIN., LL.D. (HON.) ABERD., F.R.C.P. LOND., F.R.S.

GENTLEMEN,—The desire for knowledge which is common to the lower animals and man, savage or civilised, and has induced members of this Congress to come from the ends of the earth in order to gain information must have led primitive man from the earliest times to study the great problems of physiology, the nature of life, of growth, of reproduction, and of death, as well as to notice the connexion of the latter with mechanical injuries, such as the wounds inflicted by clubs and spears or by the teeth and claws of wild beasts. Next to the problems of physiology come those of pharmacology, by which I mean the poisonous or remedial action of various substances—mineral, vegetable, or animal. A knowledge of this subject is found even amongst the lowest savages and is of the greatest use to them, for it enables them, on the one hand, to avoid eating things which may cause discomfort, pain, or death, and, on the other, to obtain food by poisoning waters and thus catching fish, or by poisoning their arrows to kill game which would otherwise escape. Closely associated with the knowledge of the poisonous is that of the curative powers of herbs, and it is possessed by animals as well as man, for cows avoid noxious plants, and dogs will every now and again eat grass apparently as medicine. Primitive peoples use various substances as remedies in disease with more or less success, and one of the most extraordinary points in their practice is that they seem to some extent to have forestalled the newest researches on venins, anti-venins, and organo-therapy, for in Africa the bushmen are accustomed to drink the poison of venomous snakes as a prophylactic against their bite, and the Hausas prevent hydrophobia by killing the mad dog and making the man it has bitten eat its liver. The occurence of death from wounds or poison is intelligible even to a savage, but when illness and death occur independently of these, men naturally attribute them to invisible powers. Thus the Dyaks of Borneo ascribe sickness to wounds from invisible spears wielded by invisible spirits, and during an epidemic of disease in the middle ages the cry often arose that the wells had been poisoned. These crude ideas contain germs of truth, and when we look at Professor Metchnikoff's drawings of a Daphnia attacked by a Monospora we seem to recognise the invisible darts of the Dyaks, while during an epidemic of typhoid fever we have often to acknowledge that our wells have been poisoned by bacilli.

It is impossible to trace the steps by which the crude ideas of savage peoples regarding physiology, pharmacology, and pathology, have grown into definite sciences, or even to indicate the most important landmarks, though we naturally think of the names of Alkmaon, Galen, and Harvey in physiology; of Nicander, Magendie, and Bernard in pharmacology; and of Morgagni, Virchow, and Pasteur in pathology. During this century these three sciences have developed with almost incredible rapidity, a complete knowledge of them is enough to tax severely the most retentive memory, and it is almost impossible for any individual to keep up with the advance of all three of them. But just as the whole subject of astronomy became suddenly simplified by a change of standpoint at the very time when cycles and epi-cycles became most bewildering, so at the very time when these three sciences are becoming most complex and diverse they appear to be tending to unification and simplification. Pathology, for example, is now becoming to a great extent a branch of pharmacology, for while a few years ago its chief object was to discover, examine, and classify the microbes which give rise to disease, it is now striving rather

Digitized by Google

to discover the nature and actions of the ferments and poisons which they form, and by which they are able to cause disease and death in the animals they attack. Pharmacological investigation, instead of being confined to the alkaloids and other poisons formed by higher plants, has now extended to those formed by microscopic plants or microbes, and thus comes to include a great part of pathology. In the same way, though pharmacology is a branch of physiology, inasmuch as it deals with the phenomena of life as modified by drugs, yet physiology may, to a certain extent, be regarded as a branch of pharmacology, because some of the latest researches regarding the processes of life have been made by pharmacological methods, using the products of animal life instead of vegetable poisons. Amongst the pioneers in this line I may mention my two masters, Kühne and Ludwig, the former of whom by his chemical investigations has enabled us to differentiate the various products of albuminous decomposition, whilst the latter, with his pupils Schmidt-Mühlheim and Wooldridge, discovered the poisonous action of albumoses and peptones, and of the juices of various tissues when injected directly into the blood.

Before the proteid constituents of our food can be absorbed they must be split up during digestion into albumoses and peptones; yet these researches show that the very substances which are necessary to repair waste and are indispensable for the continuance of life prove fatal when introduced into the body in a wrong way or in too great quantity. But the products of the digestion of albumin do not normally enter the circulation as albumoses and peptones. During absorption they undergo changes of a synthetic nature in the walls of the intestine, and probably to a certain extent also in the liver, so that they again form harmless substances, and their poisonous properties are destroyed before they enter the general blood stream. But how is it that the ferments which decompose albuminous food and form poisons from it in the intestines do not pass into the blood and kill the animal by digesting the tissues and forming poisons from them? Of course pepsin cannot do so as it only acts in an acid medium, but there is no such hindrance to the action of trypsin, and yet it does not destroy the tissues composing the body itself. In all probability the reason why digestive ferments do not digest the tissues is not that they are destroyed in the digestive canal or yet that they are not absorbed, but that they are altered from active enzymes into inert zymogens which can be stored up without risk, and can again liberate active enzymes when these are required to digest a subsequent meal. In this respect they may be compared to the knives used by wandering peoples to cut up their meat, and which are not thrown away after each meal, but are simply put into sheaths which cover their edges and deprive them for a time of their cutting power.

But it is not in the intestine only that enzymes are found; they are also poured into the blood by the pancreas and probably by the thyroid and other glands. As our acquaintance with the processes of cell life increases it seems more and more likely that the tissue change on which functional activity depends is effected by enzymes, and the truer do the speculations of Van Helmont appear—that life is a process of fermentation. There can be little doubt that if enzymes in a free state were to circulate through the body they would do much harm, and, indeed, we may regard this as well-nigh proved in regard to the enzyme of tetanus. But their action is limited either by their conversion into zymogens or their localisation to the cells or tissues where their action is required. This is more readily seen in plants than in animals, and one of the best examples of it is that in germinating wheat. In the ordinary state of the grain the diastatic ferment is kept apart from the starch by a small layer of cellulose, through which the diastase cannot pass, but during germination another ferment appears which has the power of dissolving cellulose, and by breaking down this dividing membrane it allows the diastatic ferment to act upon the starch, and renders it available for the needs of the growing plant.

Enzymes appear to differ amongst themselves nearly as much as albumin, albumoses, and peptones. Some are easily separated from the cells in which they exist, whilst others are so closely united to the protoplasm that their separate existence apart from it has been denied. The yeast plant, for example, yields an invert enzyme which can be extracted with comparative ease, but the enzyme which splits up sugar into alcohol and carbonic acid is so firmly attached to the protoplasm of the cell that it is only within the last few months that it has been isolated by Buchner by the application of enormous pressure. It is probable that the enzymes contained in the cells of animal tissues differ in like manner, and that by the use of similar methods we may obtain a number of enzymes with which we are at present unacquainted. But it is not merely the products formed in the digestive canal or in the organs of animals during life, or even the alkaloids that are formed by the higher plants, that act as poisons. The processes of life are much the same in the lowest microbes as in animals or in the higher plants, and these microbes, by forming ferments and poisons, give rise to disturbance of function or death in animals. When grown in suitable media outside the body they produce enzymes and poisons, albumoses and alkaloids, and many of them continue to do so after their introduction into the body.

One of the most curious points, both in the chemistry of the higher plants and of microbes, is that they tend to form at the same time a poison and its antidote. In Calabar bean, for example, we find there are two poisons—physostigmine and calabarine, the former tending to paralyse the spinal cord and the latter to stimulate it, so that each poison to a certain extent antagonises the other. The same condition is found even more markedly in jaborandi, of which the two alkaloids pilocarpine and jaborine antagonise one another's action so that, although pilocarpine generally greatly predominates, it might be possible to get a specimen of the leaf having no action at all, although it contained a quantity of alkaloids. When injected into animals the toxins formed by microbes and the venins of serpents cause the production of antitoxins and anti-venins, which neutralise their action apparently by chemical combination in somewhat the same way as an acid and alkali, each poisonous by itself, combine to form a comparatively inert salt. But the two components here, like an organic acid and a mineral base, are unequally affected by destructive agencies, and the anti-venin may be destroyed, so that the venin again regains its activity. The conversion of zymogens into enzymes may be compared to the freeing of venins from their compounds, while the conversion of active venins into inert bodies by combination with anti-venins suggests that a similar process may occur in the case of active enzymes, by which they may be converted into inactive zymogens.

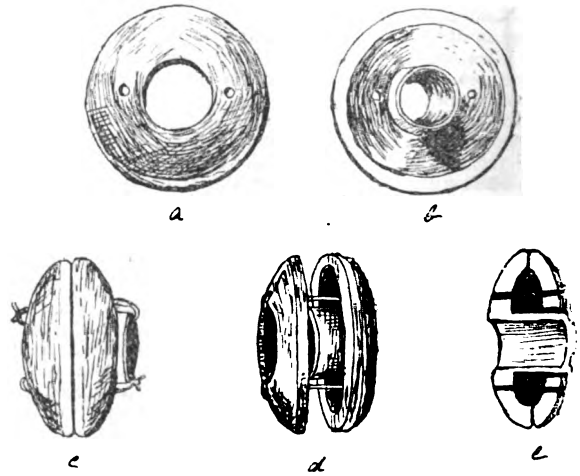
Perhaps the hypothesis I mentioned eight years ago to my pupil and friend, Mr. Hankin, that the germicidal power of organisms is proportional to their power to produce enzymes, may not be altogether unfounded, and possibly we may discover also that immunity, natural or acquired, is nothing more than an extension to the cells of the tissues generally of a power which is constantly exercised during digestion by those of the intestine and liver. This problem is one which pertains to all three sciences and has a most important bearing on practical medicine.

Practical medicine, except when empirical, depends for its advance on physiology, pharmacology, and pathology. A knowledge of the physiology of digestion has led to the satisfactory treatment of dyspepsia by the administration of digestive enzymes, and pharmacological research has enabled us to treat diseases of the circulation with a success previously undreamed of, by teaching us not only how to use aright old remedies, such as digitalis, but also how to apply new ones, such as strophanthus and amyl nitrite, and even to manufacture others, such as nitro-erythrol, which possess the special actions we desire but which are lacking in the drugs we already have. Indeed, new remedies, which shall alter tissue change, lower temperature, relieve pain, and procure sleep, are now being made in such numbers that it is hard to keep count of them. But amongst all the new gains of practical medicine none are so remarkable as those which we owe to pathology. Time would fail me to speak of the prevention and cure of zymotic diseases, but no less astonishing is the discovery that myxœdema depends on inactivity or absence of thyroid gland, and can be cured by the administration of its extract, which seems to act as an enzyme on living tissues, so that the heavy, shapeless features of the patient resume their natural expression, and the sluggish mental processes become quickened. An exhaustive study of enzymes and their products appears to be the most promising way of advancing our knowledge both of the nature and treatment of disease. Probably more is to be hoped for from an investigation into the nature and properties of those enzymes which are intimately associated with the protoplasm of the cells in the various tissues and organs than even of

Digitized by Google

those which are poured into the blood by glands having an internal secretion, such as the thyroid. For all organs, even those which like muscles and nerves are not glandular, have an action on the blood comparable to that of the yeast plant, which modifies the fluid in which it lives by the substances which it removes from or adds to it. It is to a knowledge of the processes which occur in the protoplasm of the cells in the intestinal wall and liver and of the enzymes by which these processes are in all probability carried out that we must look for an explanation of the conversion of the poisonous albumoses formed during digestion into innocuous albumins, and of dangerous enzymes into harmless zymogens. Moreover, it seems to me that it is by researches into the nature and action of the enzymes not only of microbes, but in the various tissues of the body in higher animals, that we shall learn how the microbes, like the enzymes of the intestinal canal, produce poisonous albumoses, and how the tissues, like the cells of the intestinal walls or liver, convert them into harmless or even protective substances. In this way we may hope to obtain an explanation of toxins and antitoxins, of pathogenesis and immunity, as well as of the nature of diseases unconnected with the presence of microbes, such as diabetes. Twenty three years ago I attempted to obtain a glycolytic enzyme from muscle, in order to enable diabetic patients to utilise the sugar in their blood. My attempt was unsuccessful, but we may still hope that by other methods we may obtain from animal organs various enzymes, the administration of which may prove as useful in other diseases as the thyroid gland in myxœdema.

Practical medicine depends on physiology, pharmacology, and pathology, but all three are tending to become more and more sub-divisions of the wider and all-embracing science of chemistry. It is to a chemist, Pasteur, that we owe the wonderful development of pathology within the last quarter of a century, and we may fairly regard his fellow-countryman, Lavoisier, as the founder of this science. Men from all countries, and especially from Germany, have aided its development; but it seems fitting that at this Congress, in acknowledging our obligations to this science, we should not omit to mention that at its head now stands a Russian, Mendeleef, whose marvellous prescience enabled him to predict the existence of elements which were then unknown, and even to describe their properties more correctly than those who first verified his predictions by obtaining the substances themselves. When we consider that little more than a hundred years have elapsed since the time of Lavoisier, and contemplate the vast benefits which medicine and its allied sciences have derived from chemistry during this time, our hopes cannot be otherwise than great for the centuries to come.



DECALCIFIED IVORY DISCS FOR END-TO-END AND LATERAL ANASTOMOSIS OF THE INTESTINE.[1]

BY DR. R. MARTIN GIL,

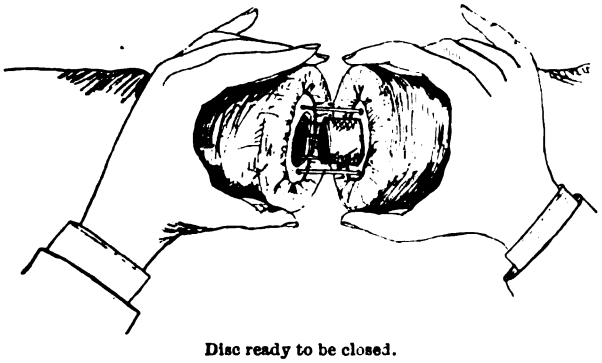
MEDICAL DIRECTOR OF THE "NOBLE" HOSPITAL OF MALAGA; CORRESPONDING MEMBER OF THE ROYAL ACADEMIES OF MEDICINE OF MADRID AND BARCELONA, ETC.

OF late years many eminent surgeons have made a special study of intestinal surgery with the result that important improvements have been effected in the treatment with a correspondingly greater number of successful operations. These improvements notwithstanding have not yet reached such a state of perfection as in other operations on the abdomen. The chief objection to Murphy's button is that a foreign body is introduced into the intestine, which may, if not expelled with the motions, itself prove a source of great danger to the patient. It is doubtless for this reason that the anastomotic button has not come into general use in Europe, and when some operators do employ it it is because they have nothing better to use. These buttons further possess the dangerous property of causing stenosis in the place where they are applied to the bowel, for the reason that the circumference of the button is usually smaller than that of the place where it is fixed. Dr. Murphy states that with his system there is no need for suture, which assertion is somewhat at variance with the facts, seeing that when, for instance, he carries out pylorectomy he is obliged to make two sutures, one in the duodenum and another in the pylorus. The same happens in ileo-colostomy after excision of the cæcum, and, finally, in the three sizes in which they are constructed the buttons are too large for the diameters of the bowel of children, which is a great drawback, as obstructions are very common during childhood. Neither can the system of using decalcified bones of different forms be recommended, as in no case where they are employed can suture be dispensed with, and the operation becomes too prolonged. The majority of operators employ suture alone, giving the preference to that of Czerny-Lembert. I have for a long time sought for a substance which should join the serous coat of the bowel and be ultimately digested after producing a perfect cicatrisation, but without giving rise to any stenosis whatever. For over three years my researches have lasted, and after vainly trying ox bones, the ribs of whales, and other substances, I thought of decalcifying pieces of ivory of different sizes, so that they might be large enough for my purpose after being prepared, as ivory, like bone, becomes reduced to half its dimensions under decalcification. I had some pieces of decalcified ivory turned in concavo-convex shapes (*Fig.* 1, A B), and of different sizes, from 8 millimetres

FIG. 1.

Decalcified ivory discs; (*d*) stretched apart to show the elastic; (*c*) in section.

to 6 centimetres in diameter. One piece is furnished with a short hollow stem or shank, to which the other piece is adjusted. The thickness of the pieces is proportioned to their circumference Beside the central hole there are two other very small orifices through which thin elastic bands pass that serve to join the pieces, thus forming a disc, as in C These bands exercise a moderate pressure intended to produce atrophy of the tissue placed between the two pieces while not causing gangrene of the intestine. These bands are tied together with a firm knot, while the ends, to avoid the loosening of this knot before cicatrisation takes place, are also bound together with a silk thread.



Method of operating; end to-end junction of the intestine.—The bowel is gently emptied by the fingers at the point of operation and clamps are applied. When the bowel is cut through a continuous suture is inserted in it at one end; a cup is introduced, the mouth of the bowel is drawn together, and the thread is tied. At the outer end the same thing is done, and the cups are drawn together by the elastic bands, thus producing a perfect junction of the serous coats of the two ends of the bowel. A portion of the ileum was resected in a dog and the ends joined by the discs. The time spent on the anastomosis of the bowel was six minutes, and the whole operation lasted eighteen minutes. The animal rapidly convalesced, and in four days was well. Three weeks later I operated again and removed the piece of intestine where the junction had been effected. No trace of the disc could be found, and no constriction of the bowel had occurred. When very large discs are required I use three or four elastic bands to ensure their fitting together all round the circumference of the bowel.

Ileo-colostomy (end-to-end anastomosis) had not previously been possible without employing sutures, but by my method this result is obtained as effectually as in other operations. A cup of corresponding diameter is fixed in the ileum, and in the colon another of larger size to adapt itself to its circumference. On the union of the two cups drawn together by the elastic bands the adjustment of the ileum to the colon is perfect. In one experiment the cæcum was resected and a cup 8 millimetres in diameter inserted in the ileum, and one of 12 millimetres in the colon, the larger cup having no central stalk; the two pieces of bowel were easily approximated, and after the operation, which lasted five minutes, the dog recovered completely. A fortnight later

FIG. 2.

Disc ready to be closed.

the abdomen was opened and a perfect cicatrix without any stenosis was found. The same method is employed in gastro-enterostomy, in which a large cup is inserted into the stomach and a small one into the duodenum. The junction of the two serous coats is thus complete. Lateral anastomosis is effected quite as easily. Cholecystenterostomy is performed with discs of the sizes required, according as the operator wishes to make larger or smaller the opening between the gall-bladder and the duodenum to ensure the escape of the bile. It might happen that an extra large incision might be required in the gall-bladder to remove a bulky gall-stone; in this case a large cup might be placed in that organ and a small one in the bowel, as is done in ileo-colostomy.

The number of dogs I have operated upon is twenty-two, and on them I have made twenty-three experiments. Among these two dogs died; one after anastomosis of the ileum with the colon lived forty hours, and then died from volvulus; the other death occurred from collapse after resection of a portion of the colon.

The discs should form a collection of twenty-seven sizes, from 60 millimetres, the largest, to 8 millimetres, the smallest.

Such are the results of the experiments carried out by me with my discs of decalcified ivory. I have not yet had the opportunity of using them on human beings.

Malaga.

A NOTE ON NEUROPATHIC DYSPEPSIA AND ITS CORRELATIONS WITH DISTURBANCES OF THE RHYTHM OF THE HEART.[1]

BY A. ERNEST SANSOM, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON HOSPITAL; PRESIDENT OF THE MEDICAL SOCIETY OF LONDON, ETC.

THIS communication contains a summary of the conclusions I have arrived at from a clinical study of a large number of cases in which there were manifested perversions of the rhythm of the heart in the sense of morbid acceleration (tachycardia), irregularity of action (arhythmia cordis), or abnormally slow action (bradycardia).

Group I., Essential tachycardia.—In those cases in which there was an abnormally rapid action of the heart persisting for long periods manifestations of dyspepsia were usually absent. In 46 cases I found no notable evidence of dyspepsia, paroxysmal or persistent. It was remarkable that an individual whose heart was beating more than 200 times in a minute should manifest no symptoms of distress whatever, but be occupied with his or her usual avocation. In cases manifesting a rate of heart pulsation of 192 and of 260 per minute I have observed a perfect absence of dyspnœa and of any signs of distress, the functions of digestion being to all seeming normally performed. In one-third of my cases there were no subjective symptoms of disorder of circulation, respiration, or digestion, though the condition of rapid heart continued. In another third severe pain at the præcordium was experienced, but there was no complaint of indigestion. It is clear that dyspepsia stands in no defined relation with the degree of tachycardia.

Group II., Tachycardia associated with some of the symptoms of Basedow's (Graves's) disease.—In these cases I found gastro-intestinal symptoms to be evidenced with a high degree of frequency. The association with the recognised signs of exophthalmic goitre might be marked or slight. In 40 per cent. of my cases the three cardinal signs of the affection—exophthalmos, enlarged thyroid, and persistently rapid heart—were present. In 31 per cent. the exophthalmos was not manifested, and in 20 per cent. the symptoms occured without thyroid enlargement. Muscular tremors were manifested in the great majority of cases. The form of dyspepsia manifested in most of these cases was paroxysmal. It occurred in attacks of the nature of gastro-intestinal crisis characterised by epigastric pain, retching, or vomiting, extreme flatulence, and in some cases diarrhœa. During the intervals there were no obvious disturbances of digestion and of necessity no wasting. In another section of the cases, though in these paroxysmal dyspepsia might not be manifested, there was extreme wasting. Cases manifesting very marked wasting constitute a well-marked section in Basedow's disease, and I have found this sign to be of unfavourable import. Consecutive or concurrent changes in the heart bear no relation with the manifestations of dyspepsia. I have noted that dilatation of the heart is more frequently manifested when the degree of tachycardia is slight. Conversely, when the heart-rate exceeds 150 per minute the heart is in most cases found to be small in outline. The paroxysmal dyspepsia is in no relation with the degree of tachycardia or with the co-existing changes in the heart. I have found that a considerable number of cases of tachycardia have been initiated by influenza. In 100 cases observed by myself in which symptoms referred to the heart were consequent upon the infection of influenza I found that persistent tachycardia was manifested in thirty-seven. In many of these there were present some of the signs of Basedow's disease, and I obtained abundant evidence to show that the complete *ensemble* of the affection could be initiated by influenza. In five of the thirty-seven cases of post-influenzal tachycardia there were well-marked crises of dyspepsia. The symptoms of the attacks were flatulence, nausea, gastralgia, and diarrhœa accompanied by dyspnœa. They occurred periodically without obvious provoking cause, and in many cases were manifested during the night. The signs were so suggestive of a neurosis that I termed them "vagus storms." It is a question for consideration whether the failure of nutrition in the section of cases attended with wasting, but not with paroxysmal dyspepsia, is not also due to a disorder of the central nervous mechanism.

Group III., Paroxysmal tachycardia.—It is a matter of common experience that attacks of palpitation of the heart are frequently associated with symptoms of dyspepsia. It is a question to be debated whether in such cases the gastro-intestinal irritation is the cause which disturbs the cardiac reflex or whether both these symptoms are of central nervous origin. I have considered this question in relation with the form of paroxysmal dyspepsia which is independent of disturbances of the heart-rhythm.

Group IV., Persistent cardiac arhythmia.—As in the case of persistent tachycardia, so in that of persistent arhythmia—even in the most extreme forms—there may be no manifestations of disorder of digestion. In many cases of extreme irregularity of the heart's action, as indicated by the sphygmographic and other precise methods of investigation, there has been no evidence of bodily discomfort or of ill performance of the functions of digestion. In such cases it is of the highest importance that the attention of the patient should not be directed to the irregular action of the heart. Such

[1] Abstract of a paper read at the International Medical Congress at Moscow.

Digitized by Google

irregularity may occur for months or years without discomfort and without danger; but if the patient's mind be allowed to dwell upon the symptoms subjective discomfort and mental troubles are apt to arise. It is undoubted that dietetic errors can cause irregularity of the heart's action, and that of necessity in such cases symptoms of dyspepsia concur. I have observed cases in which tea-drinking and the eating of potatoes have been the causes of irregular action of the heart, the cardiac rhythm returning to the normal some time after the dietetic errors had been corrected. On the other hand, there have been thousands of cases in which extreme errors of diet have been unattended with any detectable alteration of the cardiac rhythm. I consider, therefore, that for a gastro-intestinal reflex to produce cardiac arhythmia there must be certain predisposing conditions. These from an experience of a large number of cases are (*a*) gout in its acute or chronic manifestation; (*b*) osteo-arthritis (arthritis deformans) and spinal cord diseases, as locomotor ataxy, in which arthritic symptoms are manifested; (*c*) disturbances of the auditory faculty and naso-pharyngeal irritations; (*d*) mental disturbances and effects of severe nervous shock; (*e*) syphilis; (*f*) influenza; and (*g*) Basedow's disease. My clinical evidence shows that in a section of the cases of Basedow's disease extreme cardiac arhythmia is manifested and not tachycardia, as in the majority. I observed two sisters with all the signs of exophthalmic goitre; the one had a very rapid heart and the other manifested extreme cardiac irregularity. In several cases in the male sex I have found an extreme irregularity, a veritable *folie du cœur*. Gastric crises occur in these cases. In many of the cases of Basedow's disease with cardiac irregularity and paroxysmal dyspepsia no primary cause can be traced.

I have had abundant evidence to prove that irregularity of the action of the heart may be the direct consequence of the infection of influenza. Whilst tachycardia was induced by such infection in 37 per cent. of my cases, arhythmia was the consequence in 25 per cent. In twelve out of thirty cases of post-influenzal cardiac arhythmia there were symptoms of paroxysmal dyspepsia. In many these attacks were of great intensity, characterised by extreme agony referred to the abdomen or to the inter-scapular regions, flatulence, diarrhœa, dryness of throat, enfeeblement of voice, and intense depression. In some of the crises there were also dyspnœa, rigors, sneezing, and a sense of suffocation as from a grip at the throat. I observed several cases in which not only irregularity of the heart's action, but also some of the associated signs of Basedow's disease, with gastric intestinal crises, were distinctly traceable to the infection of influenza. Seeing that in my category of cases there were a considerable number in which influenza had initiated well-marked disease of the spinal cord and its membranes, and considering that in some of them the symptoms decidedly indicated neuritis of the vagus, the irregularity of the cardiac rhythm as well as the associated dyspepsia I consider must be due to a disorder of the nerve mechanism of the cardiac reflex as well as that of the nerve agencies regulating digestion. It is, I think, an interesting point, and one not generally accepted, that Basedow's disease with associated tachycardia or arhythmia is not infrequently the result of the infection of influenza. The evidence of pharyngitis in other cases lends a probability that other forms of infection, occult or untraced, may be also causes.

Group V., Persistent bradycardia.—My cases show that as in other forms of disturbance of the normal rhythm of the heart so in bradycardia, when the rate of pulsations is reduced far below the normal there may be no notable deviation from the natural functions of digestion. In a man aged seventy-eight years, observed four years ago, on many occasions the maximum rate of cardiac pulsations was 40 and the minimum 28. These were associations with gout, but no marked dyspepsia and fair health was maintained though the bradycardia continued. In young subjects the rate of cardiac pulsations is seldom below 60. At the ages of nineteen, twenty-two, and twenty-four years I have found it vary from 48 to 56. In these there have been usually some dyspeptic manifestations with symptoms of general depression. In many cases there have been mental aberrations. I have noted in several cases paroxysmal attacks of dyspepsia characterised by nausea, flatulence, and epigastric pain, and in some of these sneezing and enfeeblement of voice. The intensity of the paroxysms was usually less than in the cases of tachycardia and arhythmia. The evidence clearly showed that bradycardia was a very serious condition in a considerable section of the cases. The association with epilepsy, as pointed out by Tripier, was clearly proved. In some the attacks were momentary and of the nature of *petit mal*, in others a defined epileptic seizure occurred. It seemed most probable that the epileptic paroxysm was the result of the ischæmia of the brain due to the arrest of the heart's action. In a case in which the rate of the heart's pulsations varied between 35 and 24 I could predict from the longer arrest of the heart's action that an epileptic attack would occur.

It is shown from the evidence which I have observed that extreme bradycardia may be the result of disease or injury of the cervical portion of the spinal cord. In a case under my close observation I have found a pulse-rate of 38 and 40 per minute, with occasional halts of the heart for five seconds, due, as shown by post-mortem evidence, to involvement of the vagi nerves in a malignant growth. In a considerable section of cases I have found bradycardia to be the result of influenza. In the case of a man, aged forty-six years, who was in good health until he suffered from an attack of influenza, I found the heart-rate to vary between 33 and 19 per minute. Epileptoid attacks coincided. I have had under observation eight cases of post-influenzal bradycardia in which the pulse-rates were 56 (two cases), 54, 52, 48, 40, 36, and 19 per minute. The evidence seems to me to strongly point the conclusion that the bradycardia is due to a morbid condition of the nerve structures of the cardiac reflex. There is either an irritable lesion affecting the vagi nerves or their nuclei of origin, or else a destructive lesion of the *nervi accelerantes* of the heart whereby the inhibitory influences (vagi) are left relatively in the ascendant.

Group VI., Paroxysmal bradycardia.—I have observed in a man, aged fifty-four years, attacks recurring every afternoon for ten days, characterised by a reduction of the habitual heart-rate of from 72 to 48 per minute and coincidently severe epigastric pain, nausea, and extreme depression. The attacks ceased suddenly and the normal heart's action was resumed. In a second case, a man aged forty-six years, the pulse-rate of 80 fell to 56 and 40 per minute coincidently with abdominal pain, vomiting, and diarrhœa, constipation alternating. Both cases were post-influenzal. A complete restoration to normal conditions took place. In seven out of sixteen cases of bradycardia there were decided associations with dyspepsia.

Group VII., Paroxysmal dyspepsia without disturbances of the cardiac rhythm.—In many cases, both male and female, I have observed a train of symptoms, apart from any form of organic disease, which indicate a dyspepsia of neuropathic origin. In a man, aged twenty-four years, a typical athlete of splendid physique, there were periodic crises of severe epigastric pain with vomiting and complete anorexia. Extreme wasting occurred, the patient losing 47 lb. in weight. In a woman, aged forty years, there were similar symptoms with great wasting. In many cases there were alternations of these severe attacks and migraine. In some cases the tendency to the attacks existed from childhood and no determining cause could be traced. Heredity was no doubt a factor. In a considerable number influenza was a potent aggravating or disposing cause.

Conclusions.—1 Essential tachycardia is not accompanied by dyspepsia. 2. Paroxysmal tachycardia and the forms of tachycardia accompanied by signs, even slight, of Basedow's disease are very frequently associated with crises of dyspepsia. 3. Extreme cardiac arhythmia often occurs without manifestations of dyspepsia. 4. Gastro-intestinal irritations do not produce cardiac arhythmia without the concurrence of predisposing causes. 5. Cardiac arhythmia often replaces tachycardia in Basedow's disease. In such cases paroxysmal dyspepsia is frequent. 6. Well-marked bradycardia may exist without signs of dyspepsia. 7. Paroxysmal bradycardia is associated with crises of dyspepsia, and these crises occur in some cases of persistent bradycardia. 8. There is no defined relation between dyspepsia and the structural diseases of the heart which sometimes are manifested in cases of disturbed heart rhythm. 9. It is most probable that all forms of disturbed rhythm of the heart are due to marked affections of the nerve-element at the origin or in the course of the vagi nerves or the nerve mechanism of the cardiac reflex in the upper part of the spinal cord. 10. The attendant dyspepsia is due to an extension of the disturbance to the areas of origin or course of the gastro-intestinal branches of the vagi nerves. 11. All such alterations of the cardiac reflex nerve mechanism as well as the various disturbances of digestion

Digitized by Google

may be due to the toxic agencies of influenza or allied forms of infectious disease.

INFANTILE INTUSSUSCEPTION:

A STUDY OF ONE HUNDRED AND THREE CASES TREATED EITHER BY ENEMATA OR LAPAROTOMY, AND A REPORT OF TWO HITHERTO UNREPORTED CASES.[1]

BY FREDERICK HOLME WIGGIN, M.D.,

SURGEON TO THE NEW YORK CITY HOSPITAL, GYNÆCOLOGICAL DIVISION, BLACKWELL'S ISLAND.

IT is a strange commentary on the advancement made by our science that at the close of this nineteenth century we are met to consider and decide, if we may, upon the comparative merits of the two methods of treatment for intussusception suggested many centuries ago—that of intestinal distension by air or water by Hippocrates, and that of abdominal section by Praxagoras. For while since their time much therapeutical ingenuity in the treatment of this disorder has been displayed, our greater pathological knowledge has pushed these remedies aside, and at this time we have only left for consideration a choice between enemata and laparotomy for the relief of this condition. Some time since a case of infantile intussusception came under my observation, and the questions which were raised led me to more fully investigate this subject. It was found that, while much attention had been given in England to this form of intestinal obstruction and many cases had been recorded in the medical journals, it had received but scant attention here, and that there were comparatively few recorded cases to be found in American medical literature. The conclusion was reached that either this form of intestinal disorder is of much more frequent occurrence abroad, or that it often fails of recognition here, or that, if diagnosed and treated, it is not deemed of sufficient importance to be recorded. When it is realised that intussusception occurring in young infants is practically a hopeless condition when left to nature's care (98 per cent. of all cases terminating fatally when the immediate or remote effects of sloughing are considered), the importance of the answers to the questions, What is the scientific and, therefore, proper procedure for the relief of these little sufferers? and, What is the prospect of the infant's recovery if this method is resorted to? manifests itself, and warrants a careful consideration of the results obtained by one or other of the methods previously alluded to, and a full statement of unrecorded individual experience in the discussion. In so doing, it is evident that we must determine what foundation exists for the popular belief, both medical and lay, that the method of intestinal distension by air or water is one of safety, and that, if unsuccessful, it in no degree interferes with the performance at a later period of laparotomy, or, on the other hand, that an abdominal section performed on an infant twelve months of age or under must of necessity result fatally, and is, therefore, only to be resorted to after long delay, and the failure of the so-called milder measure to afford permanent relief. Until these questions are finally answered to the satisfaction of the profession at large it is of the utmost importance that all cases of intussusception, whether treated by one method or the other, and with whatever result, should be fully reported. In this connexion the histories of Cases 14 and 15 hitherto unreported, and the abstracts from the histories collected by the writer from the English and American medical literature since the beginning of the present century, will be of interest.

CASES OF INFANTILE INTUSSUSCEPTION SUCCESSFULLY TREATED BY ENEMATA OR INFLATION.

(GROUP NO. 1.)

CASE 1.—A case of intussusception of the ileo-cæcal variety, which occurred during 1879 in a male infant aged six months, is recorded from notes furnished to Mr. Barker by the University College Hospital.[2] The patient was admitted to the hospital thirty-one hours after the beginning of the attack. Abdominal palpation revealed a tumour. Injections of air and water were made into the bowel, causing the disappearance of the tumour, which did not again appear.

CASE 2.—Dr. Andrew records in the *St. Bartholomew's Hospital Reports* for 1892 a case of intussusception occurring in a male infant, aged four months, who came under observation on the second day of the disorder. An enema of eight ounces of water was administered. This procedure caused the apparent disappearance of the tumour, which reappeared the next day. Enemata were given hourly for nine hours, finally causing the tumour to disappear permanently.

CASE 3.—Sir William Savory records in the *St. Bartholomew's Hospital Reports* for 1892 a case of intussusception occurring in a female infant, aged twelve months, who came under observation on the first day. An enema, consisting of a pint of warm milk, was administered within nine hours after the disorder manifested itself. This treatment was followed by the apparent disappearance of the tumour, which, however, reappeared the next day. The enema was repeated with satisfactory results, and there was no recurrence of the trouble.

CASE 4.—Mr. Back[3] records a case of intussusception of the ileo-cæcal variety which occurred during 1885 in a male infant, aged five months. The case came under observation on the first day. Abdominal palpation revealed a tumour. Under chloroform narcosis an enema was administered, and while this was being done the tumour was manipulated between the finger and thumb. Reduction followed and there was no further trouble.

CASE 5.—A case of intussusception of the ileo-cæcal variety, which occurred during 1888 in a male infant, aged seven months, and who came under observation six hours after the disorder began, is recorded from notes furnished to Mr. Barker by the University College Hospital, London.[4] Injections of air and water were tried with successful results.

CASE 6.—A case of intussusception of the ileo-cæcal variety is recorded from the notes of the University College Hospital, London,[5] as having occurred in a male infant, aged nine months, during 1888, and who came under observation on the first day. Under chloroform narcosis the bowel was inflated with air, the abdomen being meanwhile manipulated. This treatment resulted in the gradual disappearance of the tumour and of all the symptoms of the disorder.

CASE 7.—The following case of intussusception of the ileo-cæcal variety occurring in a male infant, aged six months, is credited to the University College Hospital.[6] The infant came under observation within the first twelve hours of the disorder. Abdominal and rectal examination revealed a tumour. Manipulation followed by enemata of air and water were tried with partial success, but the tumour soon reappeared. Reduction was finally effected by an enema, the reservoir being elevated three feet above the patient's body.

CASE 8.—Mr Gee records[7] a case of intussusception which occurred during 1890 in a male infant aged nine months. He came under observation on the second day. Abdominal and rectal examination revealed a tumour. Enemata were administered with successful results.

CASE 9.—Dr. A. Jeffery Wood reports[8] a case of intussusception occurring in a male infant, aged six months, who came under observation on the second day. The infant, after being anæsthetised, was partly inverted and the bowel distended with air, deep massage being meanwhile employed. Under this treatment the tumour disappeared. One quart of warm water was injected into the bowel. This was followed one hour later by a stool. During the night the infant had seven dejections from the bowels, none of which contained blood The disorder did not recur.

CASE 10.—A case is recorded of intussusception of the ileo-cæcal variety occurring during 1892 in a male infant aged ten months.[9] Abdominal examination revealed a tumour. The bowel protruded from the anal orifice. Inflation was tried with success, the tumour disappeared, and the infant recovered.

CASE 11.—Dr. Beeston records[10] a case of intussusception occurring in a male infant, aged seven months, who came under observation on the second day. Insufflations of air were tried, but proved unsuccessful. On the fourth day the patient had copious stools, and passed a piece of fleshy-looking matter having a putrid odour. There was no further trouble.

CASE 12.—Dr. D. J. Caddy records[11] a case of ileo-cæcal intussusception occurring in a female infant, aged six months, who came under observation on the first day. Abdominal palpation revealed a tumour. The infant passed blood from the anus and vomited soon after she was first seen. Water was forcibly injected into the rectum, causing the apparent disappearance of the tumour. Soon after one ounce of blood escaped from the rectum. The next morning the infant was again seized with colicky pains and cried violently. She passed more blood, and a further trial of enemata under increased pressure was made, with a successful result.

CASE 13.—Mr. J. T. C. Williams records[12] a case of intussusception occurring in a male infant, aged eight months, who came under observation on the first day, giving a history of intestinal derangement for one week. Examination of the abdomen showed it to be much distended, and palpation revealed a tumour. Inversion combined with massage and an enema, followed by insufflation of air, were tried, all to no purpose. Two basins were procured, each containing eight ounces of warm water. In one one and a half drachms of citric acid were placed, and in the other two drachms of bicarbonate of soda. The acid solution was thrown into the bowel through a catheter, and was followed by the alkaline solution. The catheter was quickly withdrawn, and the nates held together for several minutes. The tumour could now no longer be felt, the vomiting ceased, and a natural dejection from the bowels occurred two days later.

CASE 14. *Intussusception successfully treated by enemata.*—On June 23rd, 1894, I was requested to prescribe for a female infant, aged four months. It was stated that she had vomited the previous day, and that she was costive and very restless. As no further information was given at this time the diagnosis of indigestion was made and grey powder ordered. On June 24th a message was received to the effect that the child had had two movements of the bowels, consequently no haste was made to reach her. When she was seen the conditions were found to be different from what had been supposed, and the previous history, which was now drawn out, was as follows. The infant had been well from birth. She was nursed, but was given in addition cow's milk, to which sugar and lime water were added. She had been more or less costive from birth. Four days prior to my first visit the mother and child had taken an outing. The infant was fretful, and was in consequence jumped up and down constantly. During the evening she became more restless and vomited greenish fluid. On June 20th the infant was given castor oil, which was rejected, nothing being retained by her stomach throughout the day. An enema was administered, and a movement of the bowels resulted. On June 21st the vomiting persisted, and more oil was given, also another enema, which treatment was followed by a small stool. During the night of June 23rd the restlessness and vomiting became more marked. On June 24th a physician who was called in noticed that the restlessness was caused by colicky pains, and that a stool containing fæcal matter and bloody mucus had been passed. The parents insisted that something should be done for the infant's immediate relief, and the physician administered an enema which contained glycerine. Bloody mucus followed, and a tumour, which soon receded, protruded from the anus. When I reached the patient her bodily temperature was 102·4° F. and her pulse was 170. Palpation of the abdomen revealed a cylindrical tumour in the left inguinal and lumbar regions. It could also be felt on rectal examination. The case was diagnosed to be one of intussusception, probably of the ileo-cæcal variety. The infant was inverted and an enema given consisting of a quart of warm saline solution. The elevation of the reservoir was 3 ft. The enema was forcibly retained for some minutes, the abdomen meanwhile being palpated (not massaged) to prevent over-distension of the colon. When the liquid was allowed to escape it was found that the tumour had partly disappeared. One hour later a small fæcal movement occurred, gas escaped from the anus, and a second and larger stool was voided. Dr. J. Lewis Smith now saw the patient, and concurred in the diagnosis and the previous treatment. As the tumour had partially yielded to the former treatment it was decided to repeat it, the reservoir this time to be raised to 4 ft., and the abdomen kneaded during the administration of the enema. Under these procedures the tumour disappeared. Two hours later a small fæcal movement occurred, and five hours after the disappearance or reduction of the tumour the infant's pulse was 170 and the temperature had fallen to 101°, the face had regained its natural expression and colour, her cry was stronger, and two movements with free escape of gas had occurred. On June 25th it was noted that the infant had slept during the night, that the tumour had not reappeared, that the temperature was normal, that the abdomen was flaccid, and that three soft, yellow, pasty stools had been passed. The further convalescence was uneventful.

CASE 15. *Intussusception successfully treated by enemata.*—I am indebted for the history of the following case of intussusception to Dr. Frank Overton, of Patchogue, Long Island. He reports that during August, 1895, a female infant, aged six and a half months, came under his observation. She had been well from birth. On the morning of the first day she was visited she cried violently, and apparently had colicky pains, which were accompanied by a rise of bodily temperature. This condition yielded to treatment. A few weeks later, on Sept. 25th, 1895, the infant was again seized with severe abdominal pains, cried persistently, and refused to be nursed. The mother gave the infant castor oil and paregoric, and this treatment was followed by a natural dejection from the bowels. In the evening the child began vomiting, and presented a peculiar apathetic appearance, crying continually. Her bodily temperature was 99·5° F. and her pulse was 120. There was no abdominal distension and grey powder was ordered. Early on the morning of Sept. 26th she voided two ounces of blood, and later a smaller quantity. She now cried constantly and vomited frequently. Her temperature was 102° and her pulse was 140, and intussusception was suspected. At 7 A.M. her temperature was 103° and her pulse had risen to 180 At 9 A.M. a consultation was held. Abdominal palpation revealed the fact that there was no distension of the bowels, but that there was a localised point of tenderness in the right side just below the umbilicus, and there a small tumour was finally felt. A reservoir was filled with warm saline solution and raised 5 ft. above the infant's body, which was partly inverted. All the water possible, without causing over-distension of the colon, was injected into the bowel and forcibly retained. Massage was also applied to the abdominal wall. The child became quiet, and after five minutes had elapsed the water was allowed to escape. The tumour could now only be felt with difficulty, and the previously described procedure was repeated. After the escape of the second enema a large fæcal movement was voided containing bloody mucus. The tumour had now disappeared. The change in the patient's countenance was magical, the vomiting ceased, and she fell asleep. During the succeeding hours she was nursed freely. On Sept. 27th it was noted that the infant had slept all night, that her temperature was normal, and that a large fæcal movement which contained neither blood nor mucus was voided. Convalescence was uneventful.

CASE 16.—Dr. Ruff reports[13] a case of intussusception

occurring in a male infant, aged seventeen days, which came under observation five hours after the first seizure. The infant was partly inverted, and an enema of water given and forcibly retained for five minutes. This proving unsuccessful inflation was tried, and then alternating injections of air and water at intervals for two hours. This treatment proving ineffectual chloroform was administered, and abdominal massage practised without benefit. Morphia was given, then alternating injections of air and water at intervals for six hours. This treatment was followed two hours later by a stool, and four hours after this occurred the infant started suddenly, and the tumour could no longer be felt. There was no reappearance of the disorder.

CASES OF INFANTILE INTUSSUSCEPTION UNSUCCESSFULLY TREATED BY ENEMATA OR INFLATION.
(GROUP NO. 2.)

CASES 1 TO 8.—Mr. Gorham,[11] records eight cases of intussusception occurring in infants whose ages ranged from three to eleven months. They were all treated in the first place by purgatives, and this treatment proving ineffectual by enemata. The cases all terminated fatally.

CASE 10.—Dr. F. Taylor and Mr. Golding Bird[13] report a case of intussusception of the ileo-cæcal variety occurring during 1881 in an infant, aged eight months, who came under observation on the first day. Abdominal and rectal examination revealed a tumour, and there were blood and mucus on the diaper. The bowel was distended with air and the tumour under this treatment apparently disappeared, only to return some hours later. Chloroform was then administered, and inflation again tried with increased pressure, but without avail, as the infant soon died. The necropsy revealed the fact that the invaginated bowel remained unreduced. Forcible inflation with air was tried (without result), and then with water, which reduced the ileum, but left the colon inverted. This proved also to be gangrenous. Under the injection of water the peritoneal and muscular coats of the bowel gave way at several points, leaving the mucous coat intact.

CASE 11.—Mr. Andrews records[16] a case of intussusception which occurred during 1881 in an infant, aged four months, who came under observation on the third day. Four enemata were administered. After the last one the tumour could not be felt. On the following day the infant died. The necropsy revealed the fact that the invaginated bowel remained unreduced. No evidence of peritonitis existed.

CASE 12.—Mr. Barker records[17] a case of intussusception of the ileo-cæcal variety occurring in a female infant, aged four months, who came under observation during the first twenty-eight hours. Inversion and enemata of air and water were tried, causing the apparent reduction of the tumour, but it reappeared nine hours later. The enemata were repeated with apparent success. Two hours later the tumour could again be made out, and it was again apparently reduced by enema. The infant collapsed and died. The necropsy revealed the fact that the invaginated bowel had never been completely reduced and that it was gangrenous.

CASE 13.—Mr. Cripps records[18] a case of intussusception occurring during 1884 in a male infant, aged four months, who came under observation on the fourth day. Under chloroform narcosis an enema consisting of one and a half pints of water was administered. While this was being accomplished the infant vomited, inspired vomited material, and died. The necropsy revealed two lacerations of the bowel, probably caused by the enema.

CASE 14.—Mr. Baker records[19] a case of intussusception occurring during 1884 in a male infant, aged seven months, who came under observation on the eighth day. Two enemata were administered, and the last apparently reduced the invagination, as the tumour could no longer be felt. Five hours later, however, the infant died. No necropsy was made.

CASE 15.—Mr. Andrews records[20] a case of intussusception occurring during 1886 in a male infant, aged four months, who came under observation on the fourth day. Six enemata of oil and two of milk were administered. This treatment was followed by the infant's death. The necropsy revealed the fact that the invagination had been only partially reduced.

CASE 16.—Mr. Mortimer reports[21] a case of intussusception occurring in an infant, aged eight months, who came under observation on the fourth day. Under chloroform narcosis abdominal palpation revealed a tumour. This procedure was followed by collapse. The infant was stimulated and two enemata, each consisting of about two ounces of fluid, were administered. After the last one had escaped the tumour could no longer be felt. Opiates were given, and for two days the only symptoms were occasional expressions of pain and increasing abdominal distension. At the end of this time vomiting re-commenced and the tumour re-appeared. Chloroform was administered a second time and ten ounces of water were injected into the bowel, the reservoir being raised three feet. Following this, three enemata were administered and the tumour partially disappeared. The next day a pint of water was injected at a lower pressure than previously, and it was repeated on the succeeding day. A few hours later the infant expired. The necropsy revealed three points of rupture in the descending colon.

CASE 17.—Dr. J. Aitken Clark records[22] a case of intussusception occurring on Nov. 22nd, 1892, in a male infant, aged five months, who came under observation on the second day. Opium and enemata were administered frequently without result. The child died on the sixth day of the disease. The necropsy revealed the fact that a double intussusception remained unreduced, one at the splenic flexure and the other at the sigmoid flexure of the colon.

CASE 18.—Dr. Edward Deanesly records[23] a case of intussusception of the ileo-cæcal variety occurring in a female infant, aged seven months, who came under observation on the fifth day after the bowel protruded from the anal orifice. A history of a month's previous illness was given. Two days prior to the infant's admission to the hospital the mother returned the bowel inside the anus and gave the infant castor oil. This treatment aggravated the symptoms, the bowel again appeared outside of the anus, and a small stool containing blood was passed. The bowel was returned with ease inside the anus, and on pushing it up the ordinary abdominal tumour was recognised. An anæsthetic was administered, and was followed by an enema of one pint of water having a head of two feet, the abdomen being meanwhile massaged. After the fluid escaped the tumour could no longer be felt. The bowels were moved twice. The next day, as the infant was drowsy, the opiate was discontinued. Towards evening the infant vomited, and during the succeeding twenty-four hours the bowel once more protruded. Under chloroform narcosis it was reduced by enema, but it re-appeared the following day, when reduction was again apparently effected by enema. Twenty-four hours later death occurred. A necropsy revealed the fact that the invagination remained unreduced, and that its reduction could easily have been effected by laparotomy.

CASE 19.—Mr. Winter reports[24] a case of intussusception of the ileo-cæcal variety occurring in a female infant, aged seven months, who came under observation on the second day of the disorder. At this time a tumour protruded from the anus. Under chloroform narcosis one pint of water was injected into the bowel, the receptacle containing it being raised two feet, and the abdomen meanwhile being massaged. Under this treatment the tumour disappeared. The next day a normal stool occurred. Two days later the bowel again protruded. Chloroform was again employed, and a second enema was administered, and reduction of the tumour was apparently effected. The following day the bowel again protruded. Under chloroform narcosis an enema was given with apparently satisfactory results, but on the succeeding day the infant died. At the necropsy it was found that the bowel protruded from the anus, as it had done prior to death. The intussusception was found to lie in the exact centre of the abdominal cavity. It lay down alongside the spine, and was closely attached to it by the mesocolon, and it passed straight downwards from about the third lumbar vertebra to the pelvic outlet. The protruding mass was returned inside the rectum, and an attempt made to reduce it from above by pulling the entering part of the ileum, but it was impossible to do so. The reduction was ultimately effected with ease by encircling the bowel below the apex of

Digitized by Google

the intussusception with the thumb and finger, and holding the bowel a few inches lower down. The apex was then pushed up with the fingers. No adhesions had formed between the opposed peritoneal surfaces of the entering and returning layers.

CASE 20.—Dr. J. Aitken Clark reports[25] a case of intussusception of the ileo-cæcal variety occurring during January, 1894, in a male infant, aged nine months, who came under observation on the third day. The infant was inverted and enemata administered at short intervals, but without result, death occurring on the evening of the third day. The necropsy revealed the fact that the invaginated bowel remained unreduced.

CASES 9, 21, AND 22.—Mr. Hutchinson cites[26] three cases of intussusception within his own experience where infants were treated by enemata of air and water, which treatment was followed by death. The necropsies revealed the fact that the invaginations in all cases remained unreduced.

CASE 23.—Mr. J. D. Mortimer records[27] a case of intussusception occurring in an infant, aged three months, who came under observation on the first day of the disease. The infant had vomited and passed blood from the anus. Rectal examination revealed a tumour. The bowel was inflated with air and the tumour disappeared. Opiates were given. Some hours later the vomiting re-commenced and the abdomen became distended. Collapse followed and the infant died. The necropsy revealed the fact that the invagination had not been reduced. A tube was tied into the rectum and connected with a reservoir containing water and elevated two feet above the cadaver. The water was allowed to pass into the intestinal canal. In a few minutes the invagination was almost reduced but about one inch of the ileum, the cæcum, and part of the vermiform appendix remained tightly ensheathed in the colon. After fifteen minutes of sustained pressure the reservoir was raised from three to four feet, and a slight further reduction of the invaginated portion of bowel took place. This went no further, and in four minutes the colon ruptured in three places just below the intussusception. The invagination, though, was very readily reduced by manipulation from below without obvious damage. There was a little lymph on the peritoneal surfaces of the cæcum, and its mucous membrane was infiltrated and slightly shreddy. The valve was much swollen, and by its obstruction would probably have caused rupture at the moment of complete reduction had this been effected by the enema.

Post-mortem experiments.—Mr. Mole describes[28] some experiments made on infantile cadavers. He found that when one and a half pints of water had been injected into the bowel under a pressure of one and a half pounds to the square inch (3 ft.) the liquid passed through the ileo cæcal valve; also that air could be made to pass the same point. His conclusions were: (1) that no harm can be done to healthy intestine by enemata of fluids under a moderate pressure; (2) that hydrostatic pressure is more uniform, and therefore less likely to cause rupture of the bowel; and (3) that the part most likely to be injured by over-distension is the transverse colon.

CASES OF INFANTILE INTUSSUSCEPTION UNSUCCESSFULLY TREATED BY LAPAROTOMY.
(GROUP NO. 3.)

CASE 1.—Ashurst, in the course of an article entitled the History of Laparotomy for Intussusception,[29] states that the first laparotomy performed on an infant for the relief of an intussusception was by Gerson, and reported by Hackman, of Hamburg. The operation was performed on Sept. 18th, 1828. The subject was a male infant, aged twelve weeks. An oblique incision was made in the direction of Poupart's ligament on the left side. While effort was being made to reduce the invagination the bowel gave way at a gangrenous point, and the operation was abandoned, and the infant expired.

CASE 2.—Spencer Wells reports[30] a case of intussusception occurring in an infant, aged four months, who came under observation on the third day of the disease. The operation was performed on the following day when the infant was collapsed. The child died five hours later.

CASE 3.—Mr. Barker credits Busch[31] with a case of intussusception occurring during 1869 in a male infant, aged seven months, who came under observation on the fourth day of the acute illness. Laparotomy was performed; the invaginated gut proved to be irreducible, therefore an artificial anus was made. Death occurred eight days later.

CASE 4.—Ashurst credits Professor Weinlechner, of Vienna,[32] with a case of intussusception of the ileo-cæcal variety, which occurred during 1871 in a female infant, aged six months. Laparotomy was performed on the fourth day, and was followed by death a few hours later.

CASE 5.—A case of intussusception of the ileo-cæcal variety occurring during 1873 in an infant, aged five months, is credited by Barker to Duncan.[33] A history of several days' previous illness was given, but the day upon which the infant came under observation is not noted. Laparotomy was performed, but proved unsuccessful, death ensuing on the following day.

CASE 6.—Mr. Jonathan Hutchinson records[34] a case of intussusception of the ileo-cæcal variety occurring in an infant, aged six months, who came under observation on the third day. Enemata had previously been administered without result. The patient was collapsed and failing, therefore laparotomy was performed at once. The invaginated portion of bowel was reduced with difficulty. The case terminated fatally six hours later.

CASE 7.—Mr. Barker credits Howse[35] with a case of intussusception of the ileo-cæcal variety occurring during 1876 in an infant, aged five months, who came under observation after a month's indisposition. Laparotomy was performed. Death ensued a few hours later.

CASES 8 AND 13.—Stage is credited[36] with two cases of intussusception, one occurring during 1876 and the other in 1880. The first was a female infant, aged six months, who came under observation on the second day. Laparotomy was performed, and death ensued a few hours later. The second was a male infant, aged three months, who came under observation on the first day. Laparotomy was performed, and was followed by death two and a half days later.

CASE 9.—Mr. Smith records[37] a case of intussusception of the ileo-cæcal variety occurring during 1877 in a male infant, aged eight months, who came under observation on the fourth day, giving a history of two days' previous illness, the chief symptoms of which were abdominal pain, vomiting, and the passage of blood from the anal orifice. No tumour could be felt on making either abdominal or rectal examination. Inflation on the second day had afforded slight relief. It was tried again on the third day, and followed on the fourth day by enemata, which seemed to give some relief. Laparotomy was, however, performed on the fifth day. There were no evidences present of peritonitis, although the ileum which had slipped through the ileo-cæcal valve was gangrenous. This portion of gut was excised and an anastomosis effected. Death followed the operation five hours later.

CASE 10.—Mr. Beck is credited[38] with a case of intussusception of the ileo-cæcal variety occurring during 1877 in a female infant, aged eight months, who came under observation five and a half hours after the beginning of the attack. Repeated enemata of oil and air were administered without result, and twenty-six hours from the beginning of the disorder laparotomy was performed. The invaginated bowel, while deeply congested, was easily reduced. The operation, however, was unsuccessful, being followed by death from septic peritonitis.

CASE 11.—Sands is credited[39] with a case of intussusception of the ileo-cæcal variety occurring during 1878 in a male infant, aged six and a half months, who came under observation on the second day. Laparotomy was performed and was followed by death four hours later.

CASE 12.—Corley is credited[40] with a case of intussusception of the colic variety occurring during 1879 in an infant, aged nine months, who came under observation after several days' illness. Laparotomy was performed and was followed by death four hours later.

CASE 14.—Mr. R. J. Godlee reports [41] a case of intussusception of the ileo-cæcal variety occurring in 1882 in an infant aged fourteen weeks. Laparotomy was performed and the invagination was reduced with difficulty. The infant died, and the necropsy revealed the fact that the reduction at the time of operation was only partial.

CASE 15.—Mr. Walsham is credited [42] with a case of intussusception occurring during 1882 in a male infant, aged seven months, who came under observation on the third day. Distension of the bowel with air and water was tried. This treatment proving unsuccessful, laparotomy was performed, notwithstanding the fact that peritonitis existed. The invaginated bowel was reduced with difficulty. The operation was followed by death.

CASE 16.—Marsh records [43] a case of intussusception occurring during 1882 in a female infant, aged eight months, who came under observation on the second day. Inflation with air was employed, but without success. Laparotomy was then performed, and the invaginated bowel was easily reduced. Death ensued on the following day.

CASE 17.—Braun is credited [44] with a case of intussusception of the ileo-colic variety occurring during 1882 in a male infant, aged three months, who came under observation on the fifth day. Laparotomy was performed, and as the invagination could not be reduced it was excised and an artificial anus made. Death ensued one hour later.

CASE 18.—Dr. Kudlich and Dr. Jacobi record [45] a case of intussusception occurring during 1882 in a female infant, aged two months, who came under observation eighteen hours after the onset. Enemata and massage were first unsuccessfully employed, and were followed by laparotomy. Great difficulty was experienced in reducing the invaginated bowel, and the operation was followed by death.

CASE 20.—Mr. R. J. Godlee reports [46] a case of intussusception occurring during 1882 in an infant, aged seven months, who came under observation on the third day. Abdominal palpation revealed a tumour in the right umbilical region. Enemata of air and water were first tried without success. Laparotomy was performed under chloroform narcosis. The invagination, which proved to be of the ileo-cæcal variety, was reduced with some difficulty. The operation was followed by death, due to septic peritonitis.

CASE 21.—Symonds is credited [47] with two cases of infantile intussusception. The cases occurred during 1884. The first was of the ileo-cæcal variety and occurred in a male infant, aged five months. He came under observation on the seventh day of acute illness following thirteen days of indisposition. Laparotomy was performed and was followed by death.

CASE 22.—The second case occurred in a female infant, aged six months, and came under observation on the twentieth day of sub-acute illness. Laparotomy was performed, and was also followed by death.

CASE 23.—Mr. Beck records [48] a case of intussusception of the ileo-cæcal variety occurring during 1885 in a male infant, aged five months, who came under observation fifty-five hours after the onset. Abdominal palpation revealed a tumour. Injections of air and water were tried, but, proving unsuccessful, laparotomy was performed. The invagination proved irreducible, and the operation was abandoned. Death soon occurred.

CASE 24.—Mr. Edmund Owen reports [49] a case of intussusception occurring in a female infant on the day of her birth, who came under observation on the second day. Prior to this castor oil had been given. Digital exploration of the rectum proved the bowel to be pervious. Under chloroform narcosis an enema was administered, but without result. On the following day (3) the enema was repeated, but without affording relief. Laparotomy was performed, and the first piece of small intestine which presented in the wound was seized, and an artificial anus made. No attempt was made to find the invaginated portion of intestine. The infant survived the enterectomy six days, dying on the ninth day after birth.

CASE 25.—Horseley is credited [50] with two cases of infantile intussusception occurring during 1885. The first case was that of a male infant, aged four months, and was of the ileo-cæcal variety, and came under observation on the fourth day. Laparotomy was performed, and the intussusception proving irreducible it was excised, and an artificial anus was made. Death soon followed the operation.

CASE 26.—The second case also occurred in a male infant, and was of the ileo-cæcal variety. It came under observation nineteen hours after the onset. Laparotomy was performed. Death followed thirty hours later.

CASE 27.—Two cases of intussusception are credited to Jacobson.[51] The first occurred in 1886 in a male infant, aged five months, who came under observation with a history of three weeks' previous illness. Laparotomy was performed, and the invaginated portion of bowel was found to be partly gangrenous and irreducible. The infant's condition at this time was fairly good, but after the excision of the invaginated gut he became very bad and he soon expired.

CASE 28.—The second case occurred in an infant, aged eleven months, who came under observation with a history of a month's previous illness. Laparotomy was performed, and the invaginated portion of bowel was found to be irreducible. The operation was concluded without resection of the tumour in the hope that spontaneous cure would result by sloughing. Death ensued twenty-four hours later.

CASE 29.—Dr. Van Arsdale records [52] the fact that he had resorted to laparotomy three times in the treatment of infantile intussusception. The operation was followed by death in all of the cases. Since this report Dr. Van Arsdale has kindly furnished me with additional details of these cases. They occurred about 1887 in infants under six months of age. In one case peritonitis existed at the time of operation, and the bowels were much distended. The trouble was not satisfactorily located and the operation was incomplete.

CASE 30.—In another of the cases the intussusception was irreducible and an artificial anus was made.

CASE 31.—The same treatment was adopted in the third case.

CASE 32.—Mr. Pick records [53] a case of intussusception of the enteric variety occurring during 1887 in an infant, aged six months, who came under observation with a history of three weeks' previous indisposition, and the last two days of which had been acute. Abdominal examination revealed a tumour in the left inguinal and lumbar regions. The infant was given chloroform, inverted, and the bowel inflated with air. Under this pressure the fingers which had been placed on the abdomen over the tumour felt it suddenly melt away. Opiates were administered, but about nine hours later the infant did not appear as well, and an enema of oil was administered. On the following morning the abdomen was tender and somewhat distended. A few hours later Mr. Pick found the infant collapsed and performed laparotomy. No invagination was found, but a piece of small intestine six inches in length, which was collapsed and showed signs of having been constricted at either end, and looking paralysed. The bowel immediately below this portion of gut was also empty and collapsed. The operation was well borne, but soon after the infant suddenly collapsed and shortly died. Mr. Pick's explanation of this condition was that the first portion of gut found collapsed had been involved in the intussusception, that it had been reduced by the air pressure, but that the gut had been so long constricted that it could not recover itself after its release; therefore, the symptoms continued unchanged after the reduction.

CASE 33.—Mr. Walsham is credited [54] with a case of intussusception occurring during 1888 in an infant, aged eight months, who came under observation on the first day. Laparotomy was performed, and at the point of beginning of the invagination a small sessile tumour was found. Death followed the operation twenty-four hours later.

CASE 34.—Mr. Marsh records [55] a case of intussusception of the ileo-cæcal variety occurring during 1889 in a male infant, aged four months, who came under observation on the fourth day. A previous history of abdominal pain, vomiting, and passage of watery stools, which contained blood, was given. Abdominal and rectal examination revealed a tumour. Laparotomy was performed, and

difficulty was experienced in reducing the invaginated bowel. Death ensued a few hours later from exhaustion.

CASE 35.—Mr. Cripps records[56] a case of intussusception of the ileo-cæcal variety occurring during 1890 in a male infant, aged five months, who came under observation on the third day. A previous history of several days' illness was given, the chief symptoms of which were abdominal pain, vomiting, and the passage of blood-stained mucus from the bowel. Enemata of warm water failed twice to reduce the invagination. Abdominal and rectal examination revealed a tumour. Laparotomy was performed, and the gut was apparently reduced, but death occurred two hours later. The necropsy revealed the fact that the intussusception had been only partially reduced. There was no evidence of peritonitis.

CASE 36.—Mr. Walsham is credited[57] with a case of intussusception occurring during 1890 in a male infant, nine months of age, who came under observation on the third day. Laparotomy was performed. The invaginated bowel was easily reduced. Death followed the operation. The necropsy revealed the fact that there was a small perforation in the transverse colon and that death was due to septic peritonitis.

CASE 37.—Mr. A. E. Barker records[58] a case of intussusception occurring in an infant, aged four months, during 1891, who came under observation on the fourth day. An unsuccessful attempt to reduce the intussusception by inflation had been made. On examination the infant was found to be collapsed. A gangrenous odour was emitted. Under chloroform narcosis rectal and abdominal palpation revealed a tumour. Laparotomy was performed. The gut was found to be gangrenous and was excised and the divided ends joined. Death ensued ten hours later. The necropsy proved the sutures of the bowel to be firm, and they resisted strong pressure of water without leaking.

CASE 38.—Dr. F. J. Shepherd records[59] a case of intussusception of the ileo-cæcal variety occurring in an infant, aged seven months, who came under observation on the second day. Examination at this time revealed a dark-coloured protrusion from the anus. Laparotomy was performed under chloroform narcosis. On account of the intestinal distension the invaginated gut was found with difficulty and reduced only after the intestine had been incised. The operation was followed by the infant's death three hours later.

CASE 39.—Mr. Paul Bush reports[60] a case of intussusception occurring in an infant, aged four months, who came under observation on the third day of the disease. Enemata were administered without success. Laparotomy was performed. The intussusception proved to be of the enteric variety and irreducible. The tumour was excised and an artificial anus made. Peritonitis ensued, and the infant died twenty-four hours later.

CASE 40.—Dr. Abbé reported[61] a case of intussusception occurring during 1893, which came under observation sixteen hours after the onset. Laparotomy was performed. The invaginated bowel was reduced with much difficulty on account of the strong adhesions which had already formed. Death followed the operation twenty-four hours later.

CASE 41.—Mr. A. E. Barker records[62] a case of intussusception occurring in a male infant, aged four months, who came under observation on the third day. Abdominal and rectal palpation revealed tumour, and blood and mucus were passed from the anal orifice. Under chloroform narcosis warm water was injected in the bowel from a reservoir raised three feet above the patient's body. When five ounces had entered the fluid began to escape, and the tumour could no longer be felt. An opiate was given, and the infant slept well all night. At 6 A.M. on the following morning the child began to scream, and soon afterwards passed blood and mucus from the anus. Under chloroform narcosis laparotomy was performed, the operation occupying only eight minutes. This was succeeded by collapse and the infant died twenty-four hours later. The necropsy was negative.

CASE 42.—Dr. Briddon, at the meeting of the New York Surgical Society, held on May 23rd, 1894,[63] reported a case of intussusception occurring in an infant, aged eight months, who came under observation on the second day in a state of collapse. Laparotomy was performed. The invagination was reduced with difficulty. Death ensued five hours later.

CASE 43.—Dr. J. F. Erdmann records[64] a case of intussusception of the enteric variety occurring in January, 1895, in a male infant, aged eight and a half months, who came under observation on the fourth day. Enemata had previously been unsuccessfully employed. Laparotomy was performed, and the invaginated portion of the ileum, which proved to be in a gangrenous condition, was removed (six inches), and an end-to-end anastomosis effected by means of a Murphy's button. Septic peritonitis existed at the time of operation, and the infant died a few hours later.

CASES OF INFANTILE INTUSSUSCEPTION SUCCESSFULLY TREATED BY LAPAROTOMY. (GROUP NO. 4.)

CASE 1.—Mr. Marsh reported to the Royal Medical and Chirurgical Society at a meeting held on Dec. 14th, 1875,[65] a case of intussusception occurring in a male infant, aged six months, who came under observation on the first day of acute illness, giving a history of thirteen days of previous indisposition. Examination revealed an abdominal tumour, and there existed a protrusion from the anal orifice. Enemata of air and water were employed without success. A few hours later Mr. Marsh found the infant collapsed. Laparotomy was performed, and the invaginated bowel was readily reduced. Convalescence was uneventful.

CASE 2.—Dr. Henry B. Sands records[66] a case of intussusception of the ileo-cæcal variety occurring in a female infant, aged six months, who came under observation twelve hours after the onset. The infant was collapsed. Abdominal and rectal palpation revealed a tumour. Reduction of the invaginated bowel was first attempted by the fingers, by enemata, by the long rectal tube, by inflation, and again by enemata, and finally, as the tumour persisted in reappearing, abdominal section was resorted to. The invaginated portion of bowel was reduced with difficulty. The bowels moved two days later, and convalescence was uneventful.

CASE 3.—Mr. R. J. Godlee reports[67] a case of intussusception of the ileo-cæcal variety occurring during 1881 in an infant, aged nine months, who came under observation on the fourth day, at which time the bowel protruded from the anal orifice. The pulse-rate was 200. Inflation with air and water was first tried, after the infant had been inverted, but proved unsuccessful. Laparotomy was performed, the invaginated portion of bowel was readily reduced, and recovery ensued.

CASE 4.—Dr. Snowball records a case of intussusception of the ileo-cæcal variety occurring in an infant, aged eight months, who came under observation on the first day. Opiates and enemata having been tried unsuccessfully laparotomy was performed, and the invaginated bowel was reduced without difficulty, but the constriction was too tight to have admitted of its reduction by the enema. Convalescence was uneventful.

CASE 5.—Dr. Howitt, in a paper read before the American Association of Obstetricians and Gynæcologists in 1894, records a case of intussusception of the ileo-cæcal variety occurring during 1888 in a male infant, aged three months, who came under observation on the second day of acute illness. Abdominal palpation revealed a tumour. Cathartics had been given, aggravating all the symptoms. Under chloroform narcosis, and with the pelvis elevated, an enema was administered. When a little more than a pint had been injected the infant suddenly ceased breathing, and was resuscitated with difficulty. As the tumour had only been partially reduced by the enema laparotomy was performed. The tumour was reduced with some difficulty. The cæcum and ascending colon gave evidence of having recently been involved in the invagination. Two hours later the bowels moved, and the convalescence was uneventful.

CASE 6.—The University College Hospital records[68] a case of intussusception of the ileo-cæcal variety occurring during 1889 in a female infant, aged five months, who came under observation on the second day. Abdominal palpation under chloroform narcosis revealed a tumour. Enemata were tried

Digitized by Google

unsuccessfully. Laparotomy was performed, and the invagination was easily reduced. Convalescence was uneventful.

CASE 7.—Dr. Frederick Kammerer records[69] a case of intussusception of the ileo-cæcal variety occurring during 1889 in an infant, aged six months, who came under observation sixty hours after the onset. The infant was narcotised with chloroform, inverted, and an enema administered under strong pressure, but without result. Laparotomy was performed, and the invaginated portion of bowel was easily reduced. Recovery resulted.

CASE 8.—Sir William Savory and Mr. Marsh record[70] a case of intussusception occurring during 1890 in an infant, aged nine months, who came under observation on the second day. Abdominal palpation revealed a tumour. Laparotomy was performed, and the invaginated portion of gut was easily reduced. During the night following the operation a stool was passed which did not contain blood. Convalescence was uneventful.

CASE 9.—Mr. Paul Bush[71] records a case of intussusception occurring in an infant, aged four months, who came under observation on the second day (May 21st, 1890). Enemata had been administered without result. Under chloroform narcosis laparotomy was performed. The invagination was of the ileo-cæcal variety and was easily reduced. The patient's recovery was uneventful.

CASE 10.—Macewen records[72] a case of intussusception of the colic variety occurring during 1891 in an infant, aged nine months. When first seen the child was collapsed. Laparotomy was performed, and the invagination was with difficulty reduced, and in making the reduction the peritoneal coat of the gut was injured. Recovery ensued, and three months later the infant was shown in good health.

CASE 11.—Mr. Pollard records[73] a case of the ileo-cæcal intussusception occurring in an infant, aged six months, who came under observation on the first day. Abdominal palpation revealed a tumour. Enemata repeated at intervals were given (with a head varying from two to three feet) unsuccessfully, as the tumour kept re-appearing after short intervals. Laparotomy was performed, and the tumour was withdrawn. It seemed to consist only of the swollen ileo-cæcal valve, the intussusception having possibly been reduced by the enemata. Convalescence was uneventful.

CASE 12.—Mr. Barker records[74] a case of intussusception of the enteric variety occurring during 1893 in a female infant, aged seven months, who came under observation thirty-six hours after the onset. Abdominal palpation revealed a tumour. Enemata combined with manipulation having failed to effect reduction laparotomy was performed, and the invaginated bowel, although strangulated, was easily reduced by pressure from below. Recovery followed the operation.

CASE 13.—Mr. Verrall records[75] a case of intussusception of the ileo-cæcal variety occurring during 1894 in a male infant, aged six months, who came under observation on the first day of the acute attack. Abdominal palpation revealed a tumour. Under anæsthesia an enema of eight ounces of water was administered, the elevation of the reservoir being 2ft. This procedure had no effect on the tumour. Laparotomy was performed, and the invagination was reduced with difficulty. The bowels moved naturally the succeeding day, and the infant recovered.

CASE 14.—Dr. Beatley and Mr. Ridley record[76] a case of intussusception of the ileo-cæcal variety occurring during 1893 in an infant, aged eleven months. When the child first came under observation it was stated that the infant's bowels had been deranged for eleven days. Abdominal palpation revealed a tumour. Under chloroform narcosis enemata had been given at frequent intervals, but without result, and many hours of valuable time were thus lost. Laparotomy was performed. The tumour was reached with difficulty owing to the intestinal distension, but was easily reduced. Before the intestines could be returned within the abdominal cavity they had to be incised to allow the gas to escape. The bowels moved on the second day after the operation. The convalescence was retarded by the occurrence of a persistent diarrhœa.

[74] Brit. Med. Jour., vol. i., 1894, p. 345.
[75] Ibid., vol ii., 1893, p. 1375.
[76] Ibid., vol. i., 1894, p. 911.

CASE 15.—Mr. Lockwood records[77] a case of intussusception occurring in a male infant, aged eight months, who came under observation twenty-eight hours after the onset. Enemata were unsuccessfully tried under chloroform narcosis. The first consisted of ten ounces of water with a head of 2½ ft., and the second of twelve ounces with a head of 3 ft. Laparotomy was performed. The time required for the administration of the enemata and the performance of the laparotomy was thirty-five minutes.

CASE 16.—Mr. Barker reports[78] a case of intussusception occurring in a male infant, aged four months, who came under observation during 1894 on the second day. Abdominal palpation revealed a tumour. The infant's general condition being bad enemata were omitted, laparotomy was performed, and the invaginated bowel pressed out of the intussuscipiens. This manipulation injured the peritoneal coat in several places. The cæcum was darkly congested, swollen, and devoid of polish. The operation was followed by little shock, and the bowels moved several times during the night, each movement containing less blood. Convalescence was uneventful.

CASE 17.—Dr. Ainsley records[79] a case of ileo-cæcal intussusception occurring in a male infant, aged eight months, who came under observation on the first day. When seen the infant was collapsed. Abdominal and rectal palpation revealed a tumour. Inflation was unsuccessfully tried under chloroform narcosis, six and a half hours after the onset laparotomy was performed, and the invagination reduced. The time required for the operation was forty minutes. Commenting on this case Dr. Ainsley said: "The difficulty in unravelling the bowel, as well as its congested and œdematous condition, make us believe that had the operation been postponed even for a few hours the chances of success would have been very seriously jeopardised. I am also persuaded that prolonged inflation or injection of water could have done nothing but harm."

CASE 18.—Mr. Pollard records[80] a case of intussusception of the ileo-cæcal variety occurring in a female infant, aged seven months, who came under observation on the first day. Rectal and abdominal palpation revealed a tumour. The dejections had a gangrenous odour. Laparotomy was at once performed. The invaginated bowel was reduced with some difficulty. The infant's bowels acted naturally twenty hours later, and convalescence was uneventful.

CASE 19.—Mr. A. E. J. Barker records[81] a case of intussusception occurring in a male infant, aged five months, who came under observation during 1894. Enemata were administered with apparent success, as the tumour disappeared, but it soon returned. Laparotomy was performed and the invagination was reduced. Recovery followed the operation.

CASE 20.—Dr. Roberts records[82] a case of intussusception of the ileo-cæcal variety occurring in an infant, aged nine months, who came under observation on the fourth day. Enemata were first tried. Then laparotomy was performed and the invagination was easily reduced. The time occupied by the operation was twenty-five minutes. The infant's convalescence was uneventful.

CASE 21.—Dr. Howitt, in a paper read before the American Association of Obstetricians and Gynæcologists, 1894, records a case of intussusception of the ileo-cæcal variety occurring in a male infant, aged six months, who came under observation on the second day. Cathartics and enemata had previously been unsuccessfully employed, as was Senn's plan of rectal insufflation with hydrogen gas. The infant's condition was bad. Laparotomy was performed, and the invaginated gut was difficult of reduction. The infant's bowels moved the same evening, and his convalescence was uneventful.

REMARKS.

The total number of cases of infantile intussusception collected and reported in this paper is 103. Of these, nearly 50 per cent. occurred during the fourth, fifth, and sixth months, and in nearly equal proportions. 75·4 per cent. of the cases occurred in males, and 89 per cent. of the cases were of the ileo-cæcal variety. Pritchard in his paper on Intussusception called attention to the probable part played by external violence in the causation of this disorder during

early life, particularly the careless manner in which infants are picked up and doubled over the arm of those caring for them, thereby injuring and causing a temporary paralysis of some portion of the intestinal canal. Jacobi has also called attention to this matter, particularly to the way in which infants are violently jumped up and down to quiet their cry. This seems to have been the prime factor in the causation of the invagination in my case. The age during which the infant is most liable to be affected by this disorder seems to substantiate these views. In one case the invagination was caused by an intestinal tumour. In these cases there seems to be nothing of unusual interest in the symptomatology to record. The disorder manifests itself by means of a sudden onset of severe abdominal pain, followed by vomiting and the passage of stools containing blood and mucus. Tenesmus was present to a marked degree only in those cases where the gut protruded from the anal orifice or where the tumour was down in the rectum. The symptoms varied in intensity in the usual manner, in direct proportion to the degree of constriction the bowel was subjected to, as indicated by the character of the pain and the amount of blood passed from the anus. The sign of the disorder, an abdominal tumour, was seldom absent, as was to be expected in such a large proportion of cases of the ileo-cæcal variety. Several of the reporters call attention to the necessity in all suspected cases of this trouble of making a conjoined abdominal and rectal examination, for in some instances a tumour was revealed by this means after abdominal or rectal palpation alone had failed to discover it. A protruding anal tumour occurred in the usual proportion—about 5 per cent. of the cases. Cure by sloughing, which is exceedingly rare in these cases, was met with twice—in Beeston's case and in one recorded by Mr. Cripps in the *St. Bartholomew's Hospital Reports* for 1892, of which a few particulars will here be given, it not being included in the collection. The case occurred during 1882 in a female child, aged three months, who came under observation on the fourteenth day with a gangrenous mass of gut protruding from the anus, a portion of which was removed. The rest sloughed off and the patient recovered. Thirty-nine of the cases were treated only by means of inflation or enemata, or both. Of these sixteen, or 41 per cent., recovered. The average hour after the onset when the treatment began was the forty-first. The histories of these cases are so deficient as to the details of the quantity of fluid or the amount of pressure employed that no deductions can be drawn in regard to these points from this group. In two cases eight ounces of water were used; in two cases one pint; in two cases one quart with a head of from three to four feet; and in one case three quarts under a head of five feet was reported as having been the amount injected into the intestinal canal of an infant seven and a half months of age. In one case nine enemata were required to bring about a permanent reduction of the invagination, as evidenced by the disappearance of the tumour and the subsidence of the symptoms. Chloroform narcosis was employed in three cases while the distension of the bowel was being effected. The cases of this group which terminated fatally were twenty-three in number, a mortality of 59 per cent. The average age of the infants was about five months. The average hour following the onset when treatment was begun was the sixty-ninth. In one case while the enema was being administered under chloroform narcosis, and in the inverted position, the infant vomited, inspired the vomited material, and died. In several cases collapse followed the administration of the enema, and in nearly all cases there was the same story of the inefficiency and uncertainty of the method, the tumour disappearing only to return after a short interval, the treatment being repeated again and again, the occasional repeated administration of chloroform, and alternating injections of air or water combined with massage, often roughly applied, till finally death mercifully came to the infant's relief. In all of these cases where notes of a necropsy were found the same tale was told of gangrenous, unreduced, invaginated bowel; invaginated bowel easily reduced by internal manipulation or traction; or bowel lacerated as a result of the violence caused by the over-distension of the diseased intestine. In one instance the gut was found to have become gangrenous twenty-eight hours after the first onset.

If all the cases are counted in which intestinal distension was practised to reduce the invaginated bowel, some of which cases were afterwards treated by abdominal section, it will be found that their number is seventy-one. Of this number failure to effect reduction occurred in fifty-three instances, or 75·4 per cent., which percentage would have represented the mortality of this method of treatment had not other means been afterwards tried, taking them out of this category. These figures approximate closely those given by Hare as the percentage of mortality following this method of treatment. In one instance where laparotomy was performed after enemata had apparently failed to effect a reduction, as evidenced by a continuance of the symptoms, it was thought that the swollen ileo-cæcal valve had, after the reduction of the invaginated bowel, simulated the tumour; and in another case it was supposed that the invagination had been reduced by the distension, but that the bowel had become paralysed and had been unable to recover itself. While the experiments of Forrest, Curtiss, and others, prove that there is little or no danger of injuring healthy infantile intestine by a hydrostatic pressure of six pounds to the square inch, the experiments of Mortimer and Mole, and the practical experience set forth in this paper, demonstrate conclusively that the conditions are very much altered when one has to do with a portion of gut that has been severely constricted, even for a few hours. Battey and Mole have proved by their experiments that water under a moderate pressure can, when no obstructions exist, be made to pass through the ileo-cæcal valve, and Mole has proved that one and a half pints of water injected under a pressure of one and a third pounds to the square inch into an infantile colon will fully distend it, and that it will pass the valve. Therefore it would appear that if it is desired to treat a case of infantile intussusception by means of intestinal distension (which I freely admit after a careful study of this subject, notwithstanding the fact that the only case which has come under my personal observation was successfully treated by enemata, I would be unwilling to employ) at least one and a half pints of tepid saline solution (one teaspoonful of salt to the quart) should be placed in a reservoir which is not to be elevated above three feet; and if this is not successful after one trial the method should be abandoned and other means to effect a reduction employed. If it is thought that reduction has occurred under this method, as evidenced by the apparent disappearance of the tumour, the infant should be placed in his crib and quieted by other means than by opiates or motion, to the end that if reduction has not really been effected the effect may be made manifest by the symptoms at the earliest possible moment, so that other treatment may be attempted while the chances of a successful outcome, though diminished, are not absolutely gone. It is well to recall the fact that in those cases which were successfully treated by enemata the average hour after the onset at which treatment was begun was the forty-first, and in those cases which terminated fatally it was the sixty-ninth.

Mr. Mortimer, in the course of a paper entitled, "On the Treatment of Intussusception by Injection or Inflation and its Dangers,"[83] said "that in his opinion the chief advantage of this method of treatment lay in the slight parental opposition to its employment." In alluding to the objections of this method he said: "A serious objection to the operation (enema) is that the conditions under which it is performed can only be roughly guessed at. An invagination of a fairly healthy intestine may at one time remain unreduced, when a little more pressure would have completely unfolded it, whilst at another time a very slight force may be enough to cause rupture. There is always afterwards a deceptive lull of some hours due to effects of shock, to the anæsthetic, and cessation of feeding, as well as to the opium which is usually given. Such delay may so alter the general and local conditions as to render hopeless any further procedure. It is also true that an experienced operator may blindly do as much damage as the merest tyro. I need not dwell on the obvious value of being able to feel and see what one has to deal with both as regards the intussusception and the various complications which may accompany it. There is seldom hesitation in performing an operation, perhaps a serious one, in the most unfavourable cases, say, of ruptured aneurysm or obstructed labour, or in ascribing a fatal ending less to the operation than to the condition which necessitated it. To this class acute intussusception in the late stage belongs." In the course of the discussion which followed the report of Mr. Mortimer's case of intussusception unsuccessfully treated by enemata Mr. Bryant

said: "In my opinion under all circumstances the treatment by intestinal distension is dangerous, although successful cases may be occasionally recorded, and it is only justifiable within the first three days, and in cases not presenting symptoms of acute strangulation." The speaker also considered manipulations through the abdominal wall during the administration of enemata as being dangerous. Mr. Pritchard, in the course of his paper entitled "Intussusception,"[84] said: "I think a child would stand a far better chance of getting well after an abdominal section and the disentangling of the invagination by the fingers than by the influx of water, if the irrigator had to be elevated higher than three feet to bring about a reduction"; and, finally, Dr. Charles K. Briddon, surgeon to the Presbyterian Hospital, New York, in a recent communication to myself, said: "From what I have seen of the cases brought into hospital *in extremis* and the great difficulty of reducing the parts at that time, I should judge the use of intestinal enemas as *simply trifling* with a very grave condition, only to be combated by the institution of radical measures at the outset."

The history of the treatment of infantile intussusception by the method of intestinal distension, by either air or water, as evidenced by the testimony which has been presented, is certainly a dark page in that of our science. It is a story of empirical, rather than scientific, endeavour, one of hope deferred, of uncertainty, of prolonged torture none the less cruel because it was performed in all kindness and was generally considered to be the gentlest method of dealing with the disorder, and finally of a mortality of 75 per cent of disaster. Laparotomy was performed in this group of cases sixty-four times for the relief of infantile intussusception. It resulted successfully in twenty-one, or in 32·8 per cent., of the cases operated upon. The average age of these infants was about six and a half months. The average hour from the onset till the time of operation was the forty-fourth. In seventeen of the cases inflation and enemata, or both, had previously been tried without success. In eight cases the invaginated bowel was readily reduced, and in ten cases it was reduced with difficulty. In three of the histories nothing was stated regarding this point. The length of time required for the performance of the operation was in one instance stated to be eight minutes, and in another thirty-five minutes, which latter included the administration of an enema. Laparotomy was followed by death in forty-three of the cases, giving a mortality of 67·2 per cent. The average age of these patients was about five months, the youngest upon whom enterectomy was performed being only three days old. The patient lived six days after, probably dying from inanition, as the operator opened the first piece of bowel which presented itself in the wound. If these cases are subtracted from our list of unsuccessful abdominal sections in which either the operation was abandoned, the bowel incised and an artificial anus made or resected, and an anastomosis effected, we shall have 45 cases, of which number only 24 resulted fatally, reducing the mortality to 53 4 per cent. If we count only the operations, successful and unsuccessful, that have been performed since the perfected technique of abdominal surgery has become generally known—say, since 1889—and throwing out, as before, the cases in which the operation has not been completed, the bowel incised or excised, we have a total of 18 cases, of which 14 were successful and 4 were unsuccessful, giving a still lower percentage of mortality, or 22·2 per cent., which I believe is a fair estimate of the risk to-day of abdominal section performed on a young infant for the relief of this disorder if performed within the first forty-eight hours of the onset. It would seem that if an infant suffering from this disorder were first seen in collapse it would be wise before attempting the operation to stimulate the infant and, if the child responded, to proceed, otherwise it would be useless to do so. The operators in that case have almost invariably employed the median incision satisfactorily. The best method for reducing the invaginated portion of bowel seems to be that wherein the tumour is encircled below its apex by the finger and thumb, while the intussuscipiens or sheath is held a few inches lower down, the apex of the tumour being pushed in an upward direction. Traction from above the tumour should not be employed. If, however, the tumour proves to be irreducible (although, so far as I have knowledge, there is no recorded case of intestinal resection or an artificial anus in an infant under twelve months of age which has proved successful), it is my belief that the method devised by the late Professor H. Widenham Maunsell is the best that has been devised for treating this most unfortunate complication caused by delay.

Disastrous as the treatment of infantile intussusception by means of intestinal distension has already proved to be, the results obtained from 1828 to 1889, when abdominal section was finally resorted to, seem to have been even more so, giving as it did a higher percentage of mortality, or 84 per cent., as against 75·4 per cent. But it must be borne in mind that it was always a last resort, only employed after the little patient had become collapsed by days of severe pain, inability to take and retain food, persistent, often hourly, torture by inversion, the administration of anæsthetics, enemata of air and water, and massage, to which not unfrequently was added the so-called long rectal tube. Nothing more surely could be devised to unfit an infant or adult to withstand the nervous shock which must necessarily accompany the administration of an anæsthetic, the opening of the peritoneal cavity, and the manipulations of the intestines. As one case of section proved unsuccessful, and its result was reported, it almost certainly added danger to the next case that came under the surgeon's care. In an editorial comment in THE LANCET on a case of intussusception treated by enemata, which resulted fatally, it was said:[85] "It is true that the invagination can always be reduced—at all events in the early stages of the disease—by the operation of laparotomy, but this operation is attended by such a large percentage of mortality when undertaken in infants that the surgeon shrinks from performing it until all other means have been tried and have failed." Mr. Lawson Knaggs, in the course of an able article entitled, "Resection for Gangrenous and Irreducible Intussusception,"[86] said: "This waiting policy, this surgery of hope, has so far been a dismal failure, nor should we forget that in all cases that last chance is far too poor to be relied upon for permanent success, and that in infants it practically does not exist." Rydygier, of Cracow, in discussing intestinal invagination at the last meeting of the German Surgical Congress, held in Berlin during April, 1895, is reported to have said: "The cases are usually treated too long by internal remedies, and accordingly come too late to the surgeon. The mortality is therefore very high—75 per cent.—especially in acute cases." Further testimony or argument would seem to be unnecessary, and we must at least begin to realise the important part played by delay in these cases, as it has in all other forms of intra-abdominal disease, in affecting the prognosis unfavourably. If by this clinical demonstration of the disease, and of the results of its treatment from 1828 to 1895, the general profession and the laity could be impressed with the fact that acute intussusception is in reality a form of strangulated hernia, that the sub-acute variety is an irreducible hernia, that enemata are far from being devoid of danger in their administration, that abdominal section performed under modern conditions and during the first forty-eight hours of the disorder, with a chance of success represented by 78 per cent.—which would speedily rise to 90 per cent. as the cases came more frequently under operation during the first twenty-four hours—it would not be long before we should come to look upon the treatment of this disease by enemata of air and water much as we do to-day upon the pukes, purges, doses of metallic mercury, of gold and silver balls, of mixtures of bird-shot and olive oil, and blood-letting, which were soberly employed by good men not so many years ago for the relief of this distressing disorder, made more painful by reason of the heroic treatment considered necessary for its relief. With the light turned fully upon what modern surgery has already accomplished in this direction, it is a safe prediction that before the dawn of the twentieth century it will be generally acknowledged that our science has fully and finally triumphed over another of her malignant foes—infantile intussusception.

THE OPERATIVE TREATMENT OF DISPLACEMENT OF THE UTERUS.[1]

BY J. CURTIS WEBB, M.A., M.B., B.C. CANTAB.,
LATE HOUSE ACCOUCHEUR, KING'S COLLEGE HOSPITAL.

IN an article by Dr. Martin, of Berlin, on Anterior Colpotomy[2] he acknowledges his indebtedness to Dr. Dührssen as the originator of the operation of anterior vaginal fixation; but the operation described is not the Dührssen procedure, but a modification, and, I venture to think, an improvement thereof, which was worked out by Dr. Mackenrodt, at that time Dr. Martin's assistant. Having been for some years now the head of a clinic of his own in Berlin Dr. Mackenrodt, perceiving the great value of the operation in the treatment of the various forms of uterine displacement, has spent much labour and time in perfecting it, and I should like to express my gratitude to him for permission to publish his work in England, and also for his kindness in giving me every possible facility for working in his clinic on the two occasions on which I have visited Berlin.

The operation of vaginal fixation.—Dührssen, of Berlin, claims to be the originator of the operation of vaginal fixation in its present form, and I will therefore describe his method of procedure first, and will then discuss the important modifications introduced by Dr. Mackenrodt. I must acknowledge my indebtedness to Dr. Dührssen for his kindness in supplying me with the very full account of his operation and its result in the shape of a paper read by him before the Gynæcological Society of Vienna in the early part of 1895. He operates as follows: Having pulled the anterior lip of the cervix down to the vulva with a volsellum he curettes the uterus for the endometritis, which nearly always exists in displacements of any duration, and if the cervix is much hypertrophied he performs a low amputation, as a large cervix tends to prevent the organ remaining in the anteflexed and anteverted position in which his operation fixes it. An assistant now holds the volsellum that is drawing down the cervix, and the operator makes a transverse incision 1½ cm. long over the insertion of the anterior vaginal wall into the cervix, the upper lip of the wound is drawn upwards with a volsellum, and the incision is prolonged on each side by 1 cm. The bladder is now separated from the anterior vaginal wall and uterus by the finger inserted through the incision, and is kept out of the way during the rest of the operation by an anterior retractor. The utero-vesical fold of peritoneum is seized with a Spencer Wells' forceps and drawn down. It is opened by a sagittal incision and the edges are sewn to the edges of the vaginal wound with catgut. The body of the uterus is now drawn forward either by inserting a stout steel sound with a considerable curve through the os or by fixing a volsellum into the anterior wall as high up as can be reached, pulling that down, and then fixing another one higher up, pulling that down, and so on until the fundus is reached and drawn out of the original incision. The posterior wall of the organ can now be examined with the finger, and any adhesions torn through or burnt with a thermo-cautery; the ovaries and tubes can also be drawn out and inspected and removed if necessary; and if there be any myomata on the body of the uterus they can be enucleated. Two *silkworm* gut stitches are now passed in through the edges of the incision in the anterior vaginal wall, deep through the substance of the fundus and out through the other edge of the vaginal incision. Before tying them the vaginal incision with the attached edges of the peritoneal cut is closed by a continuous catgut suture. The cervix is now loosed from the volsellum holding it down and pushed up to its proper position, and the silkworm stitches are then tied. The vagina is packed with iodoform gauze, and the operation is complete. Dr. Dührssen says that if there are no myomata or tubal or ovarian disease to be treated he usually completes the operation in from five to seven minutes. There are two dangers to be avoided—viz., cutting one or both ureters or wounding the bladder. The first can easily occur if the initial transverse incision be made a little too long, as they pass close along the sides of the cervix before turning up to enter the trigone. The bladder was wounded only once by Dr. Dührssen; in this case he had already performed vaginal fixation some years previously, but a relapse had occurred owing to metritis and the pressure of a myoma. The uterus was 11 cm. long; after cutting through the vaginal cicatrix he tried to free the bladder, which was somewhat strongly adherent to the cervix, with the finger. In so doing he used some force as the adhesions were strong, and the bladder wall was torn and a vesico-vaginal fistula was left, which subsequently healed spontaneously. He therefore recommends that in cases where the bladder is at all firmly adherent to the cervix, as is the case in a repeated operation, the adhesions be cut through with scissors, keeping the blades very close to the uterus.

In the *Archiv für Gynäkologie*, 1894, Dr. Dührssen publishes statistics of 197 cases operated upon with one death—i.e., a mortality of about 0·5 per cent. In 4 cases the operation was started and then had to be replaced by hysterectomy; 1 died after operation. Of the remaining 192 cases there are 150 cures, varying from a few months to three years. In 12 cases, after relapse had occurred, the operation was repeated. Even in counting these 12 as failures there have been but 42 relapses, of which nearly all occurred in the first nine months and Dr. Dührssen concludes, therefore, that if a cure lasts nine months, it will probably be permanent. To sum up, then, out of 192 cases 42 have failed, leaving 150 successes, or about 77 per cent. In a communication I received from Dr. Dührssen in October, 1895, he states that in the last year and a half he has performed from 120 to 130 cases of vaginal fixation, among which was the one death referred to above and one relapse in the case of a very large uterus with several myomata, which, in spite of enucleation of the myomata, relapsed soon after the operation. All the others have done well, and there has been no relapse, and the patients have been largely or entirely relieved of their symptoms. This considerably improves the statistics I have given.

The modifications introduced by Dr. Mackenrodt in his vaginal fixation were to avoid any risk of cutting the ureters, to make the ultimate position of the uterus not so sharply anteflexed, and to employ absorbent catgut in place of the non-absorbent silkworm gut. His procedure is as follows. Having first curetted the interior of the uterus, and, if necessary, carried out an amputation of the cervix, he draws down the cervix to the vulva with a volsellum, which an assistant holds; another volsellum is now fixed in the mucous membrane of the anterior vaginal wall, about half an inch below the meatus of the urethra. By drawing on the upper and lower volsella, the anterior vaginal wall is everted and put on the stretch. A longitudinal incision is now made from one volsellum to the other, just through the mucous membrane, which is then dissected off the bladder on each side of the incision; the vesico-vaginal septum is cut through and the bladder pushed well up with the finger and kept out of the way by a rectangular retractor. The uterus is now brought forward either by means of a sound or else by grasping it with a volsellum as high up as possible through the vaginal incision and drawing it forward. A catgut stitch is passed through the vesico-uterine fold of peritoneum and deep into the substance of the body and the ends are tied, but left long; these ends are pulled down and another stitch is passed similarly higher up, and so on till the fundus is nearly reached. The object of these stitches is to attach the vesico-uterine fold of peritoneum to the body of the uterus, and so to ultimately obtain peritoneal adhesions, and Dr. Mackenrodt insists strongly on the fundus itself not being wounded. The edges of the vaginal incision are now sewn by interrupted catgut sutures to the body of the uterus to which the peritoneum has been attached, having first, of course, cut off the long ends of the primary row of stitches. The vagina is stuffed with iodoform gauze, and the catheter usually passed for the first twenty-four hours; the patient is kept in bed about a fortnight or three weeks and then allowed to get up, and can begin light work in from a month to six weeks after the operation.

The advantages, I think, of Dr. Mackenrodt's operation are:—1. That the longitudinal incision through the anterior vaginal wall does away with any risk of cutting the ureters or large vessels, and also that, in cases where the vagina is large and lax, this longitudinal incision can be converted

[1] An abstract from a thesis for the degree of M.B. Cantab.

Digitized by Google

into a rhomboidal one, and thus an anterior kolporrhaphy can be done at one and the same time as the vaginal fixation, thus strengthening the point of attachment of the uterus and curing any prolapse that may be present. 2. That by using absorbent catgut instead of non-absorbent silkworm gut, the uterus is eventually maintained in place purely by adhesions, which, in the event of subsequent pregnancy, can stretch and allow the uterus to rise out of the pelvic cavity in a normal manner. 3. That by fixing the body, and not the fundus only, the final position of the organ is not one of such extreme anteflexion as in the Dührssen operation.

In regard to the question of pregnancies following vaginal fixation both Dr. Dührssen and Dr. Mackenrodt state that after their respective operations the patients go through a normal period of pregnancy, and that no complications arise in delivery traceable to the operation. It is only right, however, to say that Dr. Mackenrodt states that he saw a case of ruptured uterus occur in a patient on whom the Dührssen operation had previously been performed, and when I was in Berlin Cæsarean section was performed on a woman who had been operated on some time before;[3] and in the out-patient department of the Charité Hospital a patient presented herself who was pregnant and on whom Dr. Dührssen had performed his vaginal fixation. Pregnancy was then about five or six months advanced; the fundus was fixed to the anterior vaginal wall; all the uterine enlargements had taken place at the expense of the posterior wall, and the cervix was drawn up quite out of reach, and, under chloroform, was found to be pointing directly backwards. The patient was sent into the hospital with a view to Cæsarean section, but I left Berlin shortly afterwards, and do not know the further history of the case. When one considers the condition of affairs maintaining after the two respective varieties of vaginal fixation, it is obvious that there is a greater possible risk after the Dührssen than after the Mackenrodt procedure, for in the former the fundus is fixed permanently by non-absorbent material (silkworm gut), and the organ is in the position of marked anteflexion with anteversion, while in the latter operation the uterus, being fixed with absorbent catgut, after a time is maintained in position only by adhesions, which can stretch with the tendency of the pregnant uterus to rise up out of the pelvic cavity, which stretching would be assisted if, as is very likely, these adhesions share in the softening of tissue that takes place in the uterus when pregnancy is in process.

Dr. Mackenrodt was originally only in the habit of opening the peritoneum when he wished to examine the tubes and ovaries for suspected disease, or to remove them if they were known to be affected and to enucleate myomata. Latterly, in case of very long-standing retroflexions or procidentia, or where the uterus from metritis or other causes was very large—in fact, in cases where there would be a more than usual tendency to relapse—he has tried opening the peritoneum, stitching the edges of the peritoneal opening to those of the incision in the anterior vaginal wall, and then sewing the body of the uterus as before. The indications which Dr. Mackenrodt gives for his operations differ from those of Dr. Dührssen in that the former operator says that where the uterus is firmly fixed by adhesions it is necessary to do a ventro-fixation, as when the uterus is pulled forward with the volsella in the tearing of the adhesions damage has been done to the broad ligaments, and even rupture of the uterine artery has occurred and total extirpation been necessary. Considering the experiences of Dr. Dührssen, however, it would seem as if, after opening the peritoneal cavity, the finger could be passed to the back of the uterus and the adhesions gently broken down to a considerable extent, and then, by bringing the organ forwards and keeping the neighbouring parts out of the way with retractors, the separation could be completed and any slight hæmorrhage checked by means of a thermo-cautery.

In the *Berliner Klinische Wochenschrift*, No. 31, 1894, Dr. Mackenrodt published the results of 75 cases of typical vaginal fixation without opening the peritoneum. Of these patients 24 have since become pregnant; there have been 13 normal labours, 2 requiring forceps, 1 artificial induction of labour for placenta prævia, 2 abortions, and 6 pregnancies, of which no accurate notes were obtainable. Of the whole 75 cases there have been 6 relapses—4 spontaneous and 2 after pregnancies. Since that publication Dr. Mackenrodt has treated 70 further cases without opening the peritoneum (of which there have been 2 cases of natural labour; 1 is now pregnant and 1 has relapsed without pregnancy), and 35 cases with opening the peritoneum, of which there has been 1 case of early delivery with turning, 1 is now pregnant, and there have been no relapses. This makes in all a total of 180 cases, of which since the operation 27 have become pregnant and have had no difficulty in the labour that might not occur to any woman, and there have been 7 relapses, or a percentage of 3·8. He has had no fatal case. In place of his original vaginal fixation Dr. Mackenrodt now largely employs a modification which he invented in October, 1895, and which he terms "vesical fixation." He commences the operation with the same longitudinal incision through the mucous membrane of the anterior vaginal wall, separates the two flaps on each side of the incision, cuts the vesico-vaginal septum, and pushes the bladder up out of the way with the finger, at the same time separating a portion of the peritoneum from the posterior surface of the bladder. There is now a fairly large pouch of peritoneum visible between the bladder and uterus. This is grasped by a volsellum and cut completely across high up, thus leaving one free edge of peritoneum on the back of the bladder and another on the front of the uterus, just below the fundus. These are sewn together with two or three catgut sutures, passing the stitches deeply into the substance of the uterus, but, of course, not entering the cavity. The free end of the vesico-vaginal septum, which normally is attached near the anterior lip of the cervix, is now sewn to the body of the uterus about the level of the internal os uteri, and the original longitudinal incision through the mucous membrane of the anterior vaginal wall is stitched with catgut. By this procedure the uterus is fixed in a normal position, being not at all anteflexed and only normally anteverted; it is freely moveable, though it cannot become retroverted (and so cannot prolapse), and only absorbent catgut being used in a short time the organ is held in its place by peritoneal adhesions alone. Since October Dr. Mackenrodt has operated thus on thirty-six patients, and so far there have been no relapses, though, of course, the time is yet too short to allow of any statistics as regards pregnancy after this procedure, though there is no reason why the results should differ from labours following the old anterior vaginal fixation.

ASEPTIC FOREIGN BODIES IN THE EYE AND ORBIT.

BY W. M. BEAUMONT, M.R.C.S. ENG.,
SURGEON TO THE BATH EYE INFIRMARY.

THE three following cases illustrate the tolerance with which the eye submits to injuries caused by aseptic foreign bodies.

CASE 1. *Foreign body in the vitreous removed by the electro-magnet.*—A young man, aged eighteen years, was using a chisel and mallet repairing an iron pipe when a minute particle of metal flew off and pierced his left eye. He suffered a certain amount of discomfort from photophobia, but did not present himself for treatment at the Eye Infirmary until Feb. 18th, 1897, a fortnight after the accident. The course of the foreign body could be traced by a scar nearly in the centre of the cornea, a second scar a little more internal on the anterior capsule of the lens, and a third still more internal on the posterior surface of the lens, the eye having been pierced in a slightly oblique direction. The scar on the cornea could scarcely be seen, but those of the lens were distinct and their opacity gradually shaded off in the substance of the lens. With the ophthalmoscope the foreign body was at once seen floating in the vitreous, rising and falling with every movement of the eye, and refracting light much as the crystals of cholesterin do in a case of synchysis scintillans. By oblique illumination it could be equally well observed, and when an electro-magnet was brought close to the eye the particle came forward against the posterior surface of the lens, and was held steadily in that position by the attractive force of the magnet. For obvious reasons this experiment was not frequently repeated. As the foreign body had been in the eye

Digitized by Google

for a fortnight and there was no opacity of the vitreous it was quite certain that the fragment of metal was aseptic; for unless it were sterile it could not have remained so long a time in such a soil without the development of pathogenic organisms or the formation of an enveloping capsule, Leber's and von Hippel's investigations having shown that inflammatory action in these cases is set up by septic matter introduced at the time of the accident. But apart from sepsis there were other considerations to be taken into account. Even if it did not give rise to trouble by becoming oxidised, still a foreign body freely moving about in the eye is always a source of danger. It was clearly necessary to remove it, and, considering the favourable conditions of the case, it was improbable that there was any risk to fear or difficulties to contend with in so doing. The patient was anæsthetised, and an incision made through the conjunctiva behind the ciliary region and between the insertions of the external and inferior recti muscles. One edge of the cut conjunctiva was then retracted and the sclera transfixed by a Gräfe's knife in such a manner that the wounds of the sclerotic and conjunctiva were at right angles to each other. Through the opening thus made the pointer of an electro-magnet was passed, but on withdrawing it the first time the foreign body did not accompany it. The second attempt was successful, and a minute chip of metal was brought away clinging to the pointer. At the same time there was a slight loss of vitreous. The conjunctiva was stitched up and a pad put over the closed lids to keep the eye perfectly at rest. Two days later the sutures were removed from the conjunctiva, the wound of which had quite healed, and in a few more days the patient was convalescent. An interesting point in the case was the fact that although the foreign body weighed but half a milligramme it acquired momentum sufficient to carry it through the cornea and lens. The opacities in the lens have not increased, and now, six months after the injury, his vision is $\frac{6}{18}$.

CASE 2. *Foreign body embedded in the ciliary region.*—A man, aged forty-two years, whilst working as a blacksmith, was struck by a piece of metal from the anvil on the right eye. He was seen within two hours of the accident (Jan. 27th, 1897), and a piece of iron was found buried in the ciliary region to the outer side of the corneal limbus. The pupil was occluded by, and the anterior chamber half full of, blood. The tension of the eye was slightly decreased (?). Removal of the foreign body by forceps was followed by smart hæmorrhage and the vitreous presented. The jagged wound was carefully washed out with sublimate solution (1 in 4000) and the edges of the torn conjunctiva brought together by silk sutures. The patient was kept perfectly at rest in bed for three days, by which time the blood in the anterior chamber had become absorbed and the conjunctival wound healed, but the pupil was somewhat oval in its horizontal diameter. Eventually his vision was $\frac{6}{9}$, and at no time was there any irritation of the other eye.

CASE 3 *Gunshot wound of the lower lid and orbit.*—On Nov. 25th, 1896, I was asked by Dr. W. H. Lush to see a man who had accidentally been shot the day previous. He complained of intense photophobia and there was much chemosis and hyphæmia of the right eye. The lower lid had been unmistakably perforated and the foreign body had then struck and pierced the ocular conjunctiva a few millimetres below the corneal margin. Noting the direction of the course it had taken through the lower lid to the eye in almost a straight line it seemed probable that the shot had also gone through the sclerotic. But there was one noteworthy point—namely, that the tension was increased rather than diminished. Ether having been administered a probe was passed into the wound, but would not travel far, the sinus appearing to take a downward direction, and it was not until the probe was bent semi-circularly that it would pass. Then holding it as a catheter it glided in without the slightest pressure being necessary. Turning it in any other direction it stopped at once, and it would have required some force to make a false passage. The shot had evidently struck the eye, and had then been deflected by the firmness of the sclera, and so skirted round the globe in the same way as a bullet will often travel round a rib. The probe went in 3·5 cm., but the shot could not be felt. The wound was washed out with sublimate, and gradually healed up, leaving him with V. = $\frac{6}{9}$

In these three cases it is probable that the foreign bodies were made aseptic by heat. They all travelled with great velocity, in the first case sufficiently so to traverse cornea and lens, and in the third the lower lid and orbital tissues. In the second case the wound was a ragged and jagged one in the ciliary region, just such an one as might be expected to result in sympathetic mischief in the other eye. But at no time was there any sign of irritation in the left, and the wound itself healed quickly. There is no doubt much truth in de Wecker's statement that frequently injured eyes have not contracted sympathetic ophthalmia in consequence of the wounds, but in consequence of the operations which have been resorted to for their relief. But this risk is now minimised by Listerism, which has done so much for wounds of the ciliary region. It seems probable that the time will come when wounds in that dangerous zone will lose in some measure their evil reputation, and operations be as little dreaded there as those in that once fatal region, the peritoneum, now are by abdominal surgeons. In experiments made by Orio[1] he found that the discharge of a gun rendered shots aseptic, and if under these circumstances they entered the eye they never became encapsuled. Tornatola, in twenty-one cases of perforating wounds of the eye by shots, only saw one case of sympathetic ophthalmia, the freedom being due, he thinks, to the antiseptic treatment of the wound and to the fact that shot fired from a gun are aseptic. "In experimental shot wounds in the eyes of rabbits and guinea-pigs the eyes retained their form and tension in eight cases out of ten when the eye had been disinfected before the injury and the wound subsequently treated antiseptically. But of twenty eyes similarly injured when no such treatment was instituted, fourteen became phthisical from irido-choroiditis, five suppurated, and but one retained its normal appearance." The probability of a wound of the eye caused by a missile from a gun, or from the anvil, or by one which has in any way been raised to a great heat being aseptic is generally recognised by those whose practice constantly brings them in contact with such cases, and its recognition is of considerable importance in prognosis: in the first place, because such a wound, if kept aseptic, will more quickly heal; and in the second place, even though it be in the ciliary region, will heal with little or no risk of sympathetic mischief arising in the other eye. In Leber's well known experiments wounds of the cornea in which the foreign body was retained caused very little reaction unless they were septic; and as long ago as 1881 both he and Snellen found micrococci in the optic sheaths of eyes enucleated for causing sympathetic disease. Their examinations were confirmed but little later by Abraham, Story, and Deutschmann, and at the present day the theory holds the field that the optic nerves are the route and micro-organisms the means by which mischief is communicated to the sound eye. Leber has asserted that sympathetic ophthalmia only occurs after infectious septic inflammation of the exciting eye. If, then, the wound is an aseptic one, and can be kept so during the healing process, there should be little risk of that disease. But at the same time this fact does not justify us in leaving a foreign body in the eye when there is a reasonable hope of removing it, for any foreign body, whether of iron or of that (ocularly) still more objectionable metal, copper, be it never so aseptic, may start an inflammation; and an inflammation once started may go on to suppuration.

Bath.

SOME UNUSUAL CASES.

BY HENRY LEE, F.R.C.S ENG.,
CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

(*Concluded from p. 189.*)

CASE 5.—A female hospital patient under my care was suddenly seized with violent pain in the stomach and died shortly afterwards. Upon inspection a pin was found in the vermiform appendix, the point of which had evidently fretted its way through the end of the appendix. The opening this made communicated with an abscess in the peritoneal cavity. In any similar case friction in order to relieve pain might do much harm.

CASE 6.—When the original Taplow Station was being built a workman fell some 20 ft. on his head. He made a very slow and imperfect recovery and was never quite

[1] Archives of Ophthalmology, xxvi., 163.

Digitized by Google

himself again. A pint of beer would make him appear intoxicated, and he remained deaf on one side. He was given some light work to do on the line, and was struck and killed by an engine. It was found that there had been an extensive fracture of the petrous portion of the temporal bone. A considerable part of the fracture had been smoothly and firmly united. In other parts there were intervals. There was no appearance of any callus having been thrown out. The preparation is in the museum of the Royal College of Surgeons of England.

CASE 7.—A private patient had long suffered from some irritation in passing urine, and had an instrument introduced. After this he passed a small calculus, and on one side of this there was an accurate mould of the openings of the spermatic ducts. It was placed in the museum of St. George's Hospital.

CASE 8.—In Norfolk one day I met a clergyman riding on horseback. During our conversation his horse suddenly became restive, and jumped about a good deal. Very soon after this gentleman told me that a small stone had passed from the urethra. In this case, as in the last, the calculus doubtless came from the prostate gland.

Queensborough-terrace, W.

REFLEX EPILEPSY.

BY WILFRED J. HARRIS, M.B.CANTAB., M.R.C.P.LOND.,
JUNIOR MEDICAL TUTOR, ST. MARY'S HOSPITAL; LATE SENIOR HOUSE PHYSICIAN, NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE.

EPILEPTIC fits associated reflexly with some cause such as irritation of a scar, a diseased eyeball, or disease of the nasal mucous membrane, have occasionally been met with. That is, such cases have developed an epileptogenous zone, analogous to Brown-Séquard's guinea-pigs rendered epileptic by hemisection of the spinal cord, and in some cases removal of the peripheral source of irritation has been followed by cessation of the fits. Dr. Hughlings Jackson[1] is of opinion that every patient subject to fits has an epileptogenous zone, that in every epileptic patient there is a "discharging lesion" somewhere in the brain, and that disturbance of the part of the periphery (cutaneous, visceral, &c.) most especially represented in this discharging lesion may provoke a fit. Sir W. Gowers,[2] on the other hand, states: "It is excessively rare for cutaneous irritation to excite a fit. Epileptogenic zones, analogous to those of Brown-Séquard's guinea-pigs are practically unknown." Two cases have hitherto been recorded of epileptic fits following a touch on the head—one by Dr. James Dunsmure[3] in 1874, and one by Dr. Hughlings Jackson[4] in 1887. Both these cases were in boys, and in each there was partial hemiplegia, more marked after the attacks. In the older case there was slight right hemiplegia, with temporary right-sided paralysis after the attacks. In Dr. Jackson's case the weakness was left-sided. In both fits were producible during sleep, and also touching any part of the head in either case, if the patient were unaware that he was going to be touched, produced a sudden fall or fit lasting a few seconds. Dr. Dunsmure's case was watched for eighteen years, the falls becoming less frequent after the onset of severe epileptic fits, and improvement was marked during the administration of bromides, as in Dr. Jackson's patient. In each case the attack began at the age of two and a half years, but the attacks, being so short in duration, momentary falls only, loss of consciousness during them could only be surmised, though it was probable. Through the kindness of Dr. Jackson I am enabled to give the details of another somewhat similar case which was under his care at the National Hospital for the Paralysed and Epileptic recently, though in this case there were never any unilateral symptoms or hemiplegia, nor were any fits ever produced during sleep.

A girl, aged five and a half years, was admitted to the National Hospital for the Paralysed and Epileptic on Nov. 10th, 1896. She was a seven-months' child, the labour having been natural, and no instruments used. The father was stated to have suffered from syphilis before his marriage. There were three other younger children, all healthy, with no history of epilepsy in the family. The patient had not had chorea, rheumatism, or scarlet fever. When three years old she had a series of convulsions during one morning, but had no further attacks until nine months previous to admission. One month before this attack she had a fall, striking the back of her head, and she was dazed for some time afterwards, though whether the fall was due to a fit could not be ascertained for certain. A month later she began to fall about especially in the morning, and at first always fell on the back of her head, though later she always fell forwards. Her parents said that the fits were always slight and momentary; her eyes turned up and the face sometimes twitched and she suddenly fell down, often striking her head or biting her lip. She had these attacks sometimes once only, sometimes a dozen during the day. After she had suffered from them for between two and three months her mother noticed that the fits were induced by touching her on the head, as by putting the hand on her forehead, or when smoothing back her hair, or in putting on her hat. If she was expecting a touch, no fit followed. On the day of her admission the nurse, in going to her to take off her hat, accidentally touched her head, and the child immediately fell forwards, the father remarking that that was what frequently happened. The same day, when her left cheek was suddenly touched without her expecting it she immediately fell forward, her eyes rolled up, and she foamed at the mouth, there being definite transient loss of consciousness, followed by crying. There was no weakness of any limb nor any sign of hemiplegia, and at no time were there any one-sided symptoms, as in both the previously recorded cases. The knee-jerks were normal and there was no affection of sensation. The eyes were normal and there was no affection of any cranial nerve. She was a quick, nervous child, but of uncertain temper, and her intelligence was probably below the normal. She was under observation in the hospital until March 7th of this year, and during her four months' stay she had numerous fits, only occasionally a day passing without one, though she was taking six grains of bromide of potassium three times daily during the whole time. All the fits except two were of nearly the same character, often occurring when she was sitting up in bed, and she would fall with some violence against the iron bed-rail, giving herself a black eye, or sometimes biting her lower lip, and generally crying afterwards, even if not hurt. The nurse noticed several fits induced by smoothing back her hair, and after her admission three sudden fits, momentary falls, followed by crying, were produced during the first month by suddenly tapping her on the head without her knowing the touch was coming. Touching her during her sleep never produced a fit or any sudden change of colour or alteration in respiration, as in the two cases referred to above. During the latter half of her stay in hospital no fit could be induced by sudden touches, the child seeming to become accustomed to the not infrequent testing, and the spontaneous fits were also slightly less numerous. Only two severe fits were seen, with general convulsion and cyanosis, one a fortnight after admission, and another ten weeks later. It is noteworthy that about this time the reflex fits produced by sudden touches ceased; and in Dr. Dunsmure's patient it was noticed that the sudden falls became less numerous when ordinary epileptic fits supervened.

A CASE OF CARBOLIC POISONING FROM THE APPLICATION OF A CARBOLIC COMPRESS TO THE SKIN.

BY R. CLEMENT LUCAS, B.S. LOND., F.R.C.S. ENG.,
SURGEON TO, AND LECTURER ON ANATOMY AT, GUY'S HOSPITAL.

IN THE LANCET of June 1st, 1895, I published, in conjunction with my colleague, Mr. Lane, two cases of severe carbolic poisoning caused by the absorption of the poison through the skin when applied for the purpose of disinfecting the skin previously to operation. The principal symptoms were those of collapse and coma, lasting several hours; but, severe as the symptoms were, both recovered. Since that

Digitized by Google

period it has been the custom in my wards to apply a 2 per cent. solution of lysol for the purpose of disinfecting the skin, and no untoward circumstance has followed the use of this agent. A constant change of dressers, however, occasionally causes an alteration in the routine of the wards, and this enables me to place on record another similar case to those already published, though less severe in character. My present house surgeon, Mr. R. P. Rowlands, happened to be my dresser at the time the other cases occurred, and so at once recognised the cause of the patient's illness, and to him I am indebted for very careful notes of the symptoms. It will be seen that this patient had been previously prepared with a lysol compress, but the operation had then to be postponed owing to the admission of an urgent case.

The patient, a girl, aged five years, was admitted into Lydia Ward, Guy's Hospital, on account of antero-external bending of the lower third of each tibia due to rickets. On July 15th, 1897, the left leg and foot were thoroughly washed and a lysol compress (2 per cent. solution) was applied in the morning, it being intended to perform an osteotomy in the afternoon, but owing to the admission of a case of strangulated hernia it became necessary to postpone the operation until the following day. At 11.45 A.M. on July 16th the limb was again cleansed and a compress of carbolic lotion (5 per cent. solution) was applied on lint. This was applied over the foot and the lower half of the leg. At 12.30 the child was crying lustily for her prohibited dinner, and she seemed to be quite well at that time. At 1.30 she was noticed to be lying back in her cot listless, pale, and sleepy. She gradually became worse, more drowsy and pale, until at 3 P.M. the house surgeon was called to see her. The child was then very pale, cold, clammy, and sweating profusely, especially about the head; the lips and tongue were of a peculiar dark colour, almost black, very different from ordinary cyanosis. The dark blood could also be seen through the pale skin, and added to the pallor of the latter a ghastly leaden undertint, which was very striking and led Mr. Rowlands correctly to interpret the cause of the symptoms. The patient was not absolutely comatose, as she could be roused by painful stimulation such as the use of a hypodermic syringe. She then threw her arms about for a moment before lapsing into her former limp and unconscious state. The limbs were flabby and could be dropped in any position, but were capable of movement under severe reflex irritation. The reflexes were all very dull and slow, that of the conjunctivæ was never absolutely lost, but very slow and feeble. The pupils were widely dilated and almost fixed. She passed her urine under her—a rare event for her—and she was sick several times. The pulse was feeble and running, almost imperceptible, and not to be counted at the wrist. The rate taken in the carotids was from 140 to 150. The heart's impulse was feeble, diffused, and displaced outwards, half an inch beyond the nipple line, and the cardiac sounds were muffled and tumbling in character. It was evident that there was considerable dilatation of the right side of the heart. The respirations were hurried and shallow, from 40 to 50 per minute. The temperature was 95° F. in the rectum. The compress was immediately removed and the limb washed. Hot bottles were applied and the child was wrapped in warm blankets Ten minims of brandy were injected hypodermically at 3 P.M , and again fifteen minims at 4 P.M. About 4.30 P.M. the patient was better; the pulse was slower and stronger, and a pink flush had displaced the ghastly pallor of the cheeks. The skin was warmer. The pupils were now contracted. The patient was again sick several times, bringing up bilious-looking fluid. At 9 P.M. the temperature rose to 97°, and the coma gradually decreased, but she was not really sensible until the following morning. The skin became dry and rough towards morning, and the pupils dilated to normal. The temperature did not rise above normal at any time. She was not delirious nor did she try to get out of bed, but remained in a state of collapse. The urine passed in the night and early on the morning of the 17th was of a peculiar smoky green colour, which darkened almost to black as it became ammoniacal. The child was again cheerful, but pale and weaker. The anæmia continued several days, but otherwise she appeared well.

The symptoms present in this case very closely resemble those present in the two cases published in June, 1895—a general appearance of shock or collapse, with cold sweating skin and actual diminution of normal temperature. With this an exceedingly rapid pulse is found, imperceptible at the wrist, but counted elsewhere it was in one case 200, in a second case 150, and in the present instance from 140 to 150 per minute. Vomiting occurred at intervals, the vomit being of a pale, dusky blue appearance. Coma was more or less complete, and often there was stertorous breathing. The pupils in the present case were at first dilated, but afterwards contracted. The heart in the case now reported was found to be dilated and overdistended, so that its apex was felt external to the nipple. Dark-coloured urine was passed after some hours. Convulsive twitchings were noticed in the other cases similar to what are seen in uræmia, and the urine was for a time suppressed. With a return of warmth the coma gradually subsides, but the patient remains for a time pale, weak, and drowsy.

Wimpole-street, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ENGLISH CHOLERA.

By R. G. STYLE, M.R.C.S. ENG.,
SURGEON TO QUEEN ADELAIDE DISPENSARY.

ON Aug. 12th, at 11 A.M., I was called to see a girl, aged seventeen years, a paper sorter by trade. On examining her I found her to be in a state of extreme collapse; the face, body, and extremities were of a leaden hue. The tongue was clean, the eyes were sunken. There was no radial pulse. The temperature was 94° F. The nails were livid and the hands were somewhat contracted. There was no abdominal tenderness or distension, the patient only complained of slight pain in the bowels; she was restless, and her countenance was peculiarly anxious-looking besides the leaden hue. The history I obtained was as follows. The previous night she had had a supper of bread, cheese, and tomatoes, and subsequently, going out for a walk, she bought and ate some fried potatoes at a fried fish shop. She went to bed at 11.30 P.M., and at 1 A.M. woke up with vomiting and had several loose evacuations. She was removed from her own bed to that of her parents, and, they state, slept quietly till 10 A.M. Shortly after this they noticed the colour of her face, and I was sent for. I administered injections of ether, and gave brandy and a diffusible stimulant mixture, ordered hot water bottles to the extremities, and a sinapism to the cardiac region. She was seen every hour till death occurred at 5.30 P.M.; she had only one stool after I saw her, which was described as frothy water. A necropsy was made twenty hours after death; rigor mortis was well developed. The brain substance was studded with ecchymoses, the sinuses were full of dark-coloured fluid blood. On opening the thorax the lungs were seen to be very collapsed, their lower edge corresponding with the fourth rib; they were congested at the bases; there were no ecchymoses. The pericardium did not contain any fluid; there were ecchymoses on it and many on the apex of the heart. The right ventricle and auricle contained clots of dark-coloured blood, typically "tarry" in character; there were ecchymoses in the right auricle; the left ventricle contained a small ante-mortem clot. The gall-bladder was full of greenish bile. The liver was normal; the spleen and both kidneys were congested. The stomach contained about a pint of reddish-coloured fluid, mostly medicine and brandy and water. The whole of the intestines, from the duodenum to the rectum, were full of a creamy-coloured, semi-flocculent, inodorous fluid. The bladder was empty. Portions of the large and small intestines and the stomach have been submitted to bacteriological examination by Dr. Klein, the result being negative; no cholera vibrio was present, but the symptoms and post-mortem evidences were so suspicious that I think I did wisely in notifying the case to the local authorities and having disinfection promptly attended to.

CASE OF ABDOMINAL WOUND, WITH PROTRUSION OF THE ENTIRE STOMACH.

By C. BUCHANAN HUNTER, M.B. GLASG.

THE following case may be of interest to those who concern themselves with abdominal surgery, in that the whole stomach protruded through a very small opening on the right side of the body, the result of an accident. The patient was a little girl, aged eight years, who was running on an errand for her mother, carrying a pint bottle in her right hand. She appears to have tripped and fallen forward on to the neck of the bottle, which caused a V-shaped wound at the lower part of the ribs, in a line with the right nipple, into the abdominal cavity. It was stated that immediately afterwards there was protrusion of something which had increased to more than twice the size of what it was at the time. She was brought to hospital two hours after the accident. The child was seen at once, when the entire stomach was found protruding, with a small part of the first portion of the duodenum. The stomach was very much distended with gas and quite tense. The child was suffering from shock slightly and a little pain. She was at once put under chloroform, the stomach and surrounding parts were cleansed with soap and water and mercurial lotion, and an attempt was made to return the displaced organ, without avail, which necessitated an incision being made about two inches long from the inner side of the wound towards the mesial line, through the abdominal wall; after this the stomach was replaced and the wound was closed. After completion of the stitches it was found that the dimensions of the original wound were three-quarters of an inch in one direction and half an inch in the other. The patient made a good recovery, the temperature being normal all the time of her residence in the hospital. The wound was dressed with iodoform and healed by first intention.

Secunderabad.

NOTE ON WIDAL'S REACTION IN THE INFANT CHILD OF A MOTHER WHO DURING GESTATION HAD CONTRACTED TYPHOID FEVER.

By H. BATTY SHAW, M.B. LOND.,
LATE HOUSE PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

THROUGH the courtesy of Dr. Ringer I have been enabled to forward for publication the following observations. A woman was admitted to the Yates Ward of University College Hospital on Feb. 22nd, 1897, with symptoms of typhoid fever. The diagnosis was confirmed by Widal's reaction, and during the patient's six weeks' stay in the hospital the test was repeated several times, and always with positive results. The patient was also found to be in about the fifth month of pregnancy. The illness followed the usual course and without complications. The patient was discharged on April 4th. The child was born on June 14th—i.e., a little more than four months after the mother came under observation. Unfortunately the blood was not tested until the child had reached five weeks of age owing to a misunderstanding on the part of the mother. On July 21st Widal's test was tried. The mother's blood reacted well and at once; the child's blood failed to give the least reaction, and a similar negative result was given by my own blood. In about twenty-one hours, however, both the latter specimens showed very slight clumping, the unaffected bacilli being, however, very active. On the 24th the mother's blood reacted very well in seven hours, and after the same interval of time, some clumping, though very little, was seen in the child's blood. No control experiment was made. On the 27th neither the mother's nor the child's blood gave typical reaction at once, and even after twelve hours' waiting only slight clumping was found in both specimens. At the end of twenty-one hours the reaction had not advanced, and without looking at the labels it was quite impossible to distinguish one specimen from another by the reaction which had occurred. A control experiment with the blood of a case of typhoid fever in another ward gave a distinct reaction at once. On the 30th the mother's blood reacted in a very short time and in about eight hours the clumping was most marked. With the same interval of time, the child's blood failed to react at all, nor when examined twenty-one hours later was there any reaction; a control experiment on another case of typhoid fever gave reaction readily and much quicker than the mother's blood did. Thus, out of the four sets of observations, two—those of July 21st and 30th—were in favour of the infant's blood not giving Widal's reaction. The other two experiments—July 24th and 27th—were not so definite; that of the 24th merely showed that there was slight reaction on the part of the infant's blood, not nearly so marked as in the case of the mother. In the experiment of July 27th the observation was valueless as it was found that the mother's blood did not react when the blood from a known case of typhoid fever reacted perfectly. In conclusion, I may say that the child was quite healthy and was being fed at the mother's breast.

ST. GEORGE'S HOSPITAL.

A CASE OF PERSISTENT HÆMOPTYSIS IN PHTHISIS RELIEVED BY VENESECTION.

(Under the care of Dr. W. EWART.)

THE extent of the employment of venesection at the beginning of the century is only equalled by its practical disuse now that the century is drawing to its close. Yet we cannot think that a practice which was held in such high estimation by the most careful physicians can have been entirely valueless. Venesection was the recognised treatment for hæmoptysis. For instance, George Burrows writes: "The treatment of hæmoptysis, occurring as an early symptom of the development of tubercles, will not essentially differ from that recommended when it results from general plethora; we must employ general bleeding until an impression is made upon the activity of the circulation and the pulmonary hæmorrhage is arrested."[1] How venesection acts it is difficult to say; the slight increase in the coagulability of the blood and the temporary diminution of blood pressure can have but little effect.

A man, aged thirty-two years, suffering from hæmoptysis, was admitted into St. George's Hospital under the care of Dr. Ewart. Six years previously he was an in-patient suffering from pneumonia and pleurisy, and two months after leaving the hospital, and also occasionally since, he has had hæmoptysis. In December, 1896, he was admitted again into the hospital on account of the same symptom. He has never had rheumatic fever, and has had no other illness. There was no family history of tubercle. On the evening of April 15th, 1897, he coughed up about half a pint of blood and went to the hospital, and was immediately admitted. It was then noticed that the pulse was strong and tense and the patient was flushed. The hæmoptysis continued, and on the evening of the day of admission he was ordered a hypodermic injection of half a grain of morphia, ice was given him to suck, and a saline aperient was ordered. On account of the patient's condition no examination of the chest was made. On April 16th the hæmorrhage still continued, and as the bowels had not acted the saline aperient was repeated and two minims of croton oil in two ounces of castor oil were given, followed by a soap and water enema. Copious evacuations ensued, but the hæmoptysis was still severe, therefore a third of a grain of morphia was given hypodermically, and this was repeated in the evening. On auscultating the chest abundant râles were heard at the right apex, where also there was a distinct

[1] A System of Practical Medicine, edited by A. Tweedie, vol. v., p. 32

Digitized by Google

increase in the vocal fremitus. On the 17th, in the morning, the hæmoptysis was somewhat less, and the saline aperient was continued. In the afternoon suddenly a large amount of blood was coughed up, and Dr. Ewart, finding that the high tension of the pulse had not yielded to the purgatives and the morphia, and bearing in mind the favourable results reported by Dr. Huggard, of Davos, determined to bleed the patient. Accordingly eight ounces of blood were withdrawn from the arm. Immediately the patient expressed himself as feeling much easier. On the 18th there was decidedly less blood in the sputum, but the cough was very troublesome and there was much expectoration. By the 23rd the expectoration had much diminished in quantity, and no blood had been noticed in the sputum since the 21st. Except for a little blood in the sputum on the 24th there was no further hæmoptysis. The cough became much less severe, but the physical signs indicating tuberculous disease at the right apex were unaltered.

WESTERN INFIRMARY, GLASGOW.

A CASE OF EXCISION OF THE CÆCUM FOR MULTIPLE FISTULÆ, WITH USE OF MURPHY'S BUTTON; RECOVERY.

(Under the care of Dr. J. CRAWFORD RENTON.)

WHATEVER may be the verdict of posterity as to the desirability of employing Murphy's buttons in intestinal anastomosis, cases like the following conclusively demonstrate that the button is a rapid and simple method for uniting two portions of bowel. The untoward occurrences which sometimes accompany the use of the button may in time be found to be preventable, or some other method to which no objections can be raised may be devised. Dr. Renton's case is especially noteworthy on account of the long duration of the fæcal fistulæ and their rapid cure by operation.

A man, aged thirty years, was admitted to Professor McCall Anderson's wards in 1891 with a hard swelling on the right iliac region, and in the absence of Professor Buchanan the patient was seen by Dr. Renton. It was agreed that an abscess had formed, and this was opened. On the second day after the operation a free discharge of fæcal matter took place. The discharge, although diminishing, never completely stopped, and in 1892 Dr. Renton attempted to close the opening by dissecting away the infected skin and closing the opening which passed into the cæcum. This diminished the opening, but the man found it troublesome, and in 1894 Dr. Renton again tried to close it, but without success. Circumstances prevented the patient from returning until July, 1896, when it having been explained to him that Dr. Renton wished to remove the diseased portion of bowel entirely, he agreed to the operation, and entered the infirmary. Assisted by Dr. Burnside Buchanan and Dr. Walker (Professor McCall Anderson was unable to be present), Dr. Renton opened the abdomen freely, and found, on clearing away all the diseased skin, that there were several openings into the cæcum, in one direction so extensive that it was decided that it must be removed. This involved a good deal of laborious dissection, but after some trouble the diseased parts were isolated along with the appendix, which was ulcerated and adherent. Having clamped the ileum and colon with the clamp made for Dr. Renton by Messrs. Down Brothers, of London, and which is shown in the accompanying woodcut, he divided the

bowel above and below the disease. The ends of the Murphy's button were now inserted in the usual manner and joined together, the mesentery being stitched with catgut and the bowel returned to the abdominal cavity. Owing to the number of previous operations, and the amount of ulcerated skin that had to be removed, the gap to be closed was considerable. This was done successfully, and the wound has healed well, leaving very slight bulging of the abdominal wall. The patient was fed on soups and barley water, and progressed favourably (passing the button with some difficulty on the seventeenth day). He was kept at rest for six weeks, which in a serious operation such as this is of great importance. At the end of three months he commenced his work, and has continued to be quite well, so that he may now be regarded as recovered.

Remarks by Dr. RENTON. — Being a non-tuberculous ulceration of the cæcum it was a favourable case for operation by excision. Murphy's button is quickly applied, and when it passes easily supplies a most efficient means of end to end union of bowel. At the same time it is fortunate that we have several ways of uniting bowel, as each case must be treated according to circumstances. It is important when using the button to be sure that it is not too tight, as it would lead to too much gangrene of the bowel and failure of the operation. The clamp used I have found very efficient, and I have pleasure in recommending it. This patient had an attack of jaundice on each occasion that he had chloroform, which is one of the results which from time to time is met with, but he is the first patient I have had who regularly has had a distinct attack.

Reviews and Notices of Books.

Pathologie und Therapie der Perityphlitis Von Dr. ED. SONNENBURG. Dritte Auflage. Leipzig: F. C. Vogel. 1897. Preis 10 Mk. (*The Pathology and Treatment of Perityphlitis* By Dr. ED. SONNENBURG. Third edition. Leipzig: F. C. Vogel. 1897. Price 10*s.*)

THIS monograph, by Professor Sonnenburg, director of the Surgical Department of the Moabit Hospital at Berlin, is one of the most useful and practical that has been written upon the subject of appendicitis, which has now quite a literature of its own. The plan of the work is excellent. An introductory chapter deals with many points of interest, as, for instance, the rarity of typhlitis stercoralis as a primary condition, the author remarking that of 230 cases operated upon by him in not one was there any typhlitis proper found, although the symptoms were such as were wont to be attributed to that condition. He does, indeed, give one case where the appendix was found to be unaffected, but a portion of the cæcal wall was inflamed and thickened. This was not due to tuberculosis or syphilis, and the cause of the lesion could not be satisfactorily explained. The outcome of wide experience upon the varying conditions found at these operations is to the effect that perityphlitis is essentially a disease of the vermiform process, usually of slow progress, often extending over years, frequently spontaneously recovering, but in the great majority extending, often characterised by acute exacerbations which ultimately lead to perforation or gangrene of the part. Thus if once affected it remains a continual source of probable discomfort and danger. Yet in some cases of relapsing typhlitis the appendix does not undergo any profound disorganisation, but apart from adhesions retains the form and character of the normal structure, some thickening of the mucous membrane alone indicating the recurrent attacks of inflammation to which it has been subjected. The classification adopted by Professor Sonnenburg is simple. He divides the main conditions met with into the three groups of Appendicitis simplex, Appendicitis perforativa, and Appendicitis gangrenosa, and his experiences enable him to subdivide those groups according to the various complications that may be met with. His records of 209 cases, each of which is detailed, and in each of which an operation was performed, comprise 51 cases of the "simple" variety, all of which recurred; 132 cases of "perforation," of which 30 died, the deaths being almost wholly comprised of those cases in which there was peritonitis (general) or multiple abscesses; and, lastly, 26 cases of "gangrenous" appendicitis, 9 of which

Digitized by Google

were fatal, all those being cases of diffuse peritonitis, the 17 recoveries having only circumscribed peritoneal inflammation.

Wounds in War: the Mechanism of their Production and their Treatment. By Surgeon-Colonel W. F. STEVENSON, A.M.S., Professor of Military Surgery in the Army Medical School, Netley. London: Longmans, Green, and Co. 1897. Price 18*s*.

FOR two reasons the surgical treatment of gunshot wounds in the wars of the future will vary much from what has obtained in the past; the science of surgery has altered, and the injuries to be treated will be modified by the changes which have been made in the weapons and projectiles employed. Bearing these facts in mind, we feel that Surgeon-Colonel Stevenson's work will be welcomed by the medical officers of the Army, Navy, Reserve Forces, and Indian Medical Service, as well as by many men in civil practice who take an interest in the subject treated. It is the only volume which has appeared in this country save the second edition of Sir Thomas Longmore's work on "Gunshot Injuries" since the teachings of Lister and Pasteur have revolutionised the treatment of wounds, and we regard it as the first work on military surgery which has been published in English of real practical utility; for good as the work of Sir Thomas Longmore was considered to be in its day, and interesting as it is from a historical point of view, yet it failed to be of the great service which we hope and think the newly issued work will be, inasmuch as the treatment recommended by Longmore was almost always indefinite and general in its tenor.

A very large portion of the newly issued volume is devoted to detailed practice and particular methods. Surgeon-Colonel Stevenson's aim has clearly been to bring to the notice of his readers the treatment which will give the best results for each injury, and is based on results already attained or on the careful consideration of the different possibilities of treatment under the most modern conditions and system of practice.

The book of rather more than 400 pages is divided into fourteen chapters, a considerable portion of the first of which is devoted to the Mechanism of Projectiles, while the second treats of Wounds by Small-arm Bullets and by Large Projectiles or their Fragments. The third chapter deals with the Primary Phenomena and Symptoms accompanying Gunshot Wounds; the fourth and fifth chapters are concerned with the Treatment of Wounds in War. In succeeding sections the following subjects are considered—Gunshot Wounds of Joints; Gunshot Wounds of the Hip-joint; Gunshot Injuries of the Diaphyses of Long Bones; Wounds of the Head; Wounds and Injuries of the Chest; Wounds and Injuries of the Abdomen; Injuries of the Pelvis; and the Effects of the use of Modern Small-arms in the Wars of the Future. In connexion with the last-mentioned topic we think the War Office authorities will do well to ponder on a well-reasoned opinion of the author when he states that it is "evident that the work of collecting the wounded at the first post of surgical assistance cannot in future be performed in European armies as at present laid down by regulation." In the final chapter, which is headed "The Geneva Convention," the nine articles of the Convention are briefly and clearly set forth, and Mr. Furley's last suggestions, pointing out the lines on which organisation should proceed to enable the civil societies to amalgamate with the Army Medical Service in time of need and give their assistance, are recapitulated.

We would specially call attention to the handling of the subject of Wounds and Injuries of the Abdomen. We regard this as the best chapter of a very useful book—best, not only from the standpoint of subject matter, but also from that of literary excellence. In discussing the treatment of penetrating wounds Surgeon-Colonel Stevenson presses on the attention of his readers the grave wrong of the "expectant" plan, and the contra-indications for the administration of opium; his pages on laparotomy are clear and valuable, and the illustrations of the method of suturing perforations in the intestine and of Maunsell's method of performing excision of a portion of the gut are excellent.

The one fault which we find in the book is the tendency to repetition—a fault which may, however, perhaps be excused in a work of this nature, intended as it is for reference often under very difficult circumstances, when many cross references would be unsuitable. We can strongly recommend the book to the Service members of our profession, and we congratulate the author on the completion of the first edition of a work which we know will prove of true utility. It is thoroughly up to date as far as it is possible for such a work to be so in the absence of statistics which only a great modern war can supply, and the author clearly indicates the lines of treatment which should be attempted and followed under the varying conditions of warfare. A pocket edition will no doubt appear later. We think a copy should form a portion of the baggage of every medical officer ordered on service.

The present edition is well indexed and freely illustrated. The diagrams and illustrations are for the most part very clear, but we doubt whether the upper part of Fig. 11 will convey much information to the reader. The type, materials, and general get-up of the book are worthy of the publishing house from which it is issued.

The Diseases of Infancy and Childhood. By EMMETT HOLT, A.M., M.D. London: Henry Kimpton. 1897.

THIS work is a substantial volume of nearly eleven hundred pages and contains two hundred and four illustrations. It is confined to the diseases of children from birth to the age of seven or eight years. Questions of surgical procedure are only considered so far as they come under the notice of the physician. Pathology and morbid anatomy, on the other hand, are dealt with in more detail than is usual in such works, because, as the author points out, the morbid processes of early life receive scant attention in ordinary pathological works. The first section consists of a concise exposition of the general care of infants, their growth and development, and the peculiarities of disease at this age. The second part is confined to the diseases of the newly born. In the third, nutrition and its disorders are fully considered, scurvy and rickets being wisely here included. The remaining sections deal seriatim with the diseases of the different systems, the specific infectious diseases, and general diseases.

The chapters on nutrition are excellent. The author points out that temporary success in artificial feeding may mean ultimate failure, and that the prolonged use of predigested foods is a mistake. Sterilisation receives sufficient notice, and stress is laid on the fact that sterilised milk requires the same modification for feeding of infants as uncooked milk. The author is rather inclined to under-estimate the danger of tuberculous milk, considering it to be a good deal exaggerated. Proprietary foods receive quite sufficient attention. Malnutrition and marasmus are rather unnecessarily considered in different chapters—since their differences are in degree rather than in kind. Diarrhœal affections are classified partly according to their severity, and partly according to the supposed anatomical distribution, of their lesions. A more general description would have been shorter and equally satisfactory. The classification of laryngeal affections is good, and fully supported by the most recent results of bacteriology. The section on diphtheria embodies a careful description of the antitoxin

Digitized by Google

treatment, with its dosage, limitations, and results, and is well up to date.

As a whole the work is distinguished by a due sense of proportion; common ailments are fully considered, while rare affections receive a shorter though adequate description. Chronic bronchitis is perhaps insufficiently noticed, and the prognosis of heart disease is neither definite enough nor quite in accordance with the views held in this country. Cervical opisthotonos, again, is passed over with scanty description. The author's style is good, and the work is pleasant reading; the illustrations are as a rule excellent, and, in spite of the few trivial details to which we draw attention, the work is, in our judgment, one of the best yet published on the subject of children's diseases.

Practical and Operative Gynæcology. By J. CLARENCE WEBSTER, M.D., F.R.C.P. Edin., Fellow of the Royal Society of Edinburgh, &c. Illustrated with fifty-four figures. Edinburgh and London: Young J. Pentland. 1896

DURING the last six years the author has been engaged in the work of teaching practical obstetrics and gynæcology in the University of Edinburgh. He says, "In this book I have recorded with some degree of elaboration the gynæcological part of my instruction." There is some excellent general advice in the chapter on case-taking—e.g., "a physician may possess great knowledge regarding the pathology and treatment of diseases of women, but he will not make great headway in the practice of gynæcology unless he ever appreciates the subtleties and peculiarities of the psychical organisation of women. Delicacy, tact, patience, and judgment must be brought into employment. Thoroughness, also, must be particularly enjoined." A man must be blessed or otherwise with extraordinary self-confidence, not to say assurance, who flatters himself that he is always able to appreciate "the subtleties and peculiarities of the psychical organisation of women." Even the youngest gynæcologist of them all might be forgiven for feeling some degree of misgiving as to his certainty in this direction. Again, no exception will be taken to the following: "Finally, downright honesty should be the motto of the physician. There is no sphere in which there has been more dishonest practice, and it is not out of place to utter a strong protest again the crime practised ["practised" here strikes us as distinctly good in relation to the profession of crime] by those who, for the sake of gain, trade on the fears which naturally fill the minds of many women when their reproductive apparatus is out of order, and who elevate into an unnecessary importance conditions which are but trifling." The intention of all this is excellent, but its application is frequently a matter of difficulty. Gynæcologists are, unfortunately, no exception to the proverbial tendency to differ affecting members of our profession. We think it would be a pity not to recognise honest differences of opinion and a mistake to be too ready to impute unworthy motives to those whose views may not coincide with our own. Still there are, no doubt, some sparks of fire in the smoke of Dr. Webster's warning.

The author's teaching seems to us to be generally reliable. There are some slips of course, and a few things are omitted that we should have expected to find. Thus "deciduoma malignum" is not to be found in the index, nor does it appear to be referred to, although many observers consider it to be a sarcoma of the body of the uterus, and thus rather gynæcological than obstetric. Again, in the description of the operative treatment of fibroids, the intra-peritoneal method is not given as it should be at the present time. The ligature of the uterine arteries outside the uterus as an indispensable step of the operation is not insisted on, in fact, the technique given seems to be more or less that of the old intra-peritoneal operation which had so high a mortality. The section on antiseptics, and the methods needed to ensure asepsis, is excellent. We see that the author rather prefers alcoholic solutions of perchloride of mercury for disinfecting the hands.

Lectures on the Action of Medicines. By T. LAUDER BRUNTON, M.D. Edin., F.R.C.P. Lond., F.R.S, Physician and Lecturer on Pharmacology and Therapeutics to St. Bartholomew's Hospital. London and New York: Macmillan and Co. 1897. Pp. 673.

THESE lectures formed the course on Pharmacology and Therapeutics delivered at St. Bartholomew's Hospital during the summer session of 1896. They are intended to give a general sketch of the mode in which drugs act upon the body, and they are arranged very much in accordance with the schedule for the examination in pharmacology which was instituted by the Royal Colleges of Physicians of London and Surgeons of England, but which was abolished before any examination had actually been held. Fortunate were the students who heard that course. We have never read a book on this subject which has given us so much pleasure. Most works on drugs and their actions are useful as works of reference, but every page of Dr. Brunton's book is interesting, and we read on for the delight of doing so, gaining numerous useful hints for treatment and refreshing our knowledge of physiology as well as of pharmacology. Let us take, for example, the action of drugs on the circulation. Some physiological points are first noticed, the effect of temperature on the heart as shown by the demonstration of a frog's heart on a heated plate, and here is noted the effect of fever on the human heart. "Just as you can recover the frog's heart from the effect of high temperature, so you can, in many cases, recover the hearts of your patients from the effect of high temperature by cooling them down. ..... By cooling the patient down you cool the blood, and thus allow the circulation to go on again." Then follow some considerations on blood-pressure, and attention is drawn to the three large channels through which the blood finds its way from the arteries into the veins, stress being laid on the vessels of the muscles, which "are so large that they will allow as much blood to pass through them in a given time as both the vessels of the skin and of the vessels of the intestines together." Regulation of blood-pressure is fully described, with many useful directions as regards treatment. Next follows a short *résumé* of cardiac disease in general and then the drugs which are usually employed. Digitalis naturally holds the first position, and an exhaustive description is given of its uses and modes of action. An instructive section is that on the four active principles of digitalis, showing that one of them, digitonin, is to a great extent antagonistic to the other three. Other drugs acting on the heart are then considered, including an account of the effects of nicotine. Students with athletic tendencies will read with especial interest the remarks on "training." The mechanical treatment of chronic heart disease has considerable space devoted to it. The much-discussed "Nauheim Treatment" is favourably reviewed provided that suitable cases are chosen. Many practitioners still consider the Nauheim treatment as quackery or at least a fad; Dr. Brunton's anecdote may well be considered by those who hold these extreme views. "I was a good deal astonished a little while ago when I recommended a patient to go to Nauheim to receive a letter from the general practitioner who had been in attendance upon him, saying that the Nauheim treatment was too new to enable him to form any opinion about it, that he did not think it was any good, and therefore he advised the patient not to

Digitized by Google

go. The man in question simply knew absolutely nothing about it; he had not taken the trouble to inquire, and so he decided upon a basis of pure ignorance." We have taken the chapters on Circulation as an illustration of the general scope of the work; as much could be said in every division. We feel that we cannot speak in too high terms of the book, but cordially recommend it to practitioners of medicine and students. The former will find ample material for help and study, whilst the latter will discover in it a welcome change from the ordinary text-book, at the same time obtaining knowledge which will be useful to them throughout the whole of their professional life.

LIBRARY TABLE.

A Contribution to the History of the Respiration of Man, being the Croonian Lectures delivered before the Royal College of Physicians in 1895, with Supplementary Considerations of the Methods of Inquiry and Analytical Results. By WILLIAM MARCET, M.D. Edin., F.R.C.P. Lond., F.R.S. London: J. & A. Churchill. 1897. Price 12*s.* 6*d.*—This handsome volume comprises a study of the intimate nature of respiration, largely based on experiment. It shows the importance of a sufficient supply of oxygen to the proper and full exercise of the functions of the body, in which the tissues themselves play an essential part. The ordinary conception of the respiratory process requires some modification, since everything points to metabolism being initiated in the tissues which demand a supply of oxygen adequate for their needs rather than evolved by the oxygen conveyed in the circulating blood. Some of the most interesting facts described are those which clearly demonstrate that the exercise of so purely psychical a function as volition depends upon absorption of a sufficiency of oxygen, so that the act of volition influences the amount of respiration, and conversely the deficiency of oxygen in the atmosphere (as at high altitudes) may have a powerful restraining influence upon the exercise of the will. The lectures with the supplementary chapter on methods will no doubt be especially studied by physiologists, but the suggestive application of respiratory training, in the form of the favourite recreation of cycling, as a remedial agency in asthma deserves the attention of the practical physician.

L'Hygiène du Cycliste. Par le Docteur O. LAURENT, Professeur à l'Université de Bruxelles. Brussels: Alfred Castaigne. 1897. Pp. 119.—Dr. Laurent recommends cycling as an admirable exercise for average individuals of both sexes, but he earnestly cautions his readers against over-fatiguing themselves, against undue effort in going up hills, and against riding at an excessive speed. About nine and a-half miles (fifteen kilometres) per hour is, in his opinion, a sufficient pace for the ordinary rider. Neither children under ten years of age nor elderly men who are unaccustomed to active exercise ought to cycle; but those who have paid due attention to their physical condition will find cycling advantageous even in advanced life, and Dr. Laurent quotes the case of Dr. Tarrier, an American practitioner eighty-nine years of age, who used a tricycle when visiting his patients. Considerable space is devoted to the subject of cycling for females. In the absence of special diseases in an acute stage the exercise is recommended both to the single, the married, and mothers of families, always with the caution that it should be used in moderation. Dr. Laurent enumerates several diseases and morbid conditions which are benefited by this form of exercise, and cyclists, whether beginners or proficients, will find in this little book a large amount of useful information.

JOURNALS AND REVIEWS.

Bristol Medico-Chirurgical Journal.—The opening article in the current number of this well-known quarterly is a valuable contribution to medical biography, being an account of the life and work of the late James Greig Smith, an obituary notice of whom appeared in THE LANCET of June 5th, p. 1567. Mr. Greig Smith was editor of the *Journal* on its first appearance in 1883, and conducted it most ably until his retirement in 1892. Some idea of his literary activity and success may be formed from the fact that his large treatise on Abdominal Surgery has reached its fifth edition, while the list of his contributions to the medical journals fills three pages. Dr. P. Watson Williams has an interesting article on Paroxysmal Tachycardia, and describes two cases; one of the patients being a man, eighty-one years of age, who had suffered from occasional attacks for at least fifty-three years, and the other being a female, sixty-two years of age, whose first attack came on about six years before Dr. Williams first saw her. He considers that the disease is a neurosis of the intra-cardiac ganglia. Mr. J. Lacy Firth describes two cases in which intracranial pressure caused death by paralysing the respiratory centre in the medulla.

Scottish Medical and Surgical Journal.—The present number has ten original articles and three full-page plates. Dr. R. S. Thomson and Dr. E. L. Marsh, of the City of Glasgow Small-pox Hospital, contribute an instructive paper on the Antitoxin Treatment of Small-pox. The serum they employed was prepared and supplied by the Health Department, Brooklyn, New York, and was named "variola antitoxic serum." It was derived from calves rendered immune to cow-pox by inoculation with vaccine lymph, not with the virus derived directly from a variolous patient. Six cases of small-pox treated with this serum in October and November, 1895, are very fully described. Five of them recovered. The sixth case was one of hæmorrhagic small-pox, and proved fatal on the ninth day. The authors are of opinion "that in no single instance did the treatment as employed by us modify the disease." Numerous references to the results of other observers are given. Mr. F. M. Caird, of Edinburgh, describes a difficult operation, in which a renal tumour weighing 3½ lb. was removed by a lumbar incision. The patient made a good recovery.

Edinburgh Medical Journal.—Dr. A. E. Garrod contributes a valuable paper on the Spectroscopic Examination of the Urine. Dr. Byrom Bramwell continues his series of lectures on Aphasia. Mr. W. Bevan Lewis describes a modified sublimate method which has given him excellent results in the staining of sections of nervous tissues. Dr. J. Cunningham Bowie recommends the treatment of asthma by intra-laryngeal injections of menthol, iodine, or oil of hop dissolved in almond oil.

Dublin Journal of Medical Science.—The principal article is Sir Richard Quain's paper on the Mechanism by which the First Sound of the Heart is Produced; it was read before the Royal Society last June and appeared in THE LANCET of June 19th, 1897.

Mercy and Truth contains an interesting historical account of the mission hospital in Kashmir and of Dr. Elmslie's labours there. There are also articles on missionary work in the land of Moab and in Central China.

Le Vélo Médical.—This paper circulates among medical cyclists and is now published weekly. A recent number contains portraits of two celebrities who are well known to be partial to this exercise, namely Professor d'Arsonval, and Dr. Lucas Championnière, the latter of whom has been photographed in company with his little son and three daughters, all five mounted on bicycles.

Analytical Records
FROM
THE LANCET LABORATORY.

GENEVA (U.S.A.) MINERAL WATER.
(AGENCY: 10A, GREEN-STREET, LEICESTER-SQUARE, W.C.)

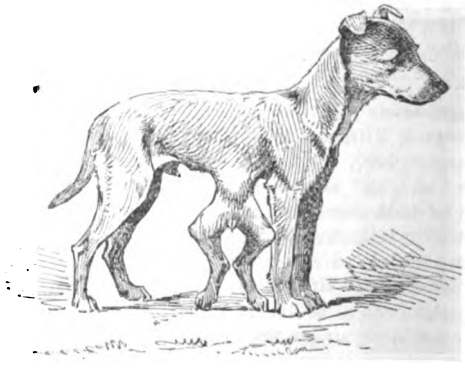
OUR analysis of this water is as follows: total solids 196 grains per gallon, of which at least 170 grains are sulphate of lime. It contains also small quantities of magnesium salts, and common salt to the extent of 4½ grains per gallon. Its total hardness exceeds that of the average London water-supply by over ten times the amount. This would condemn it, in our opinion, simply for drinking purposes, and this enormous degree of hardness is not removable on boiling. We cannot imagine upon what ground this water is offered for curative purposes. So great is the amount of calcium sulphate contained in it that it produces an immediate precipitate when mixed with alcohol. Referring to the solubility of calcium sulphate in water, we find, according to this analysis, that Geneva (U.S.A.) water is a saturated solution of this salt.

TANOCEA TEA-TONING TABLETS.
(THE TANOCEA TABLET CO., BLETCHLEY STATION.)

The composition of tanocea tablets is based upon a sound enough scientific principle, and in practice, as a matter of fact, they will be found to effect certain important improvements in the character of an infusion of tea. They are composed of gelatin and carbonate of soda, so that when placed in the teapot with a teaspoonful of leaves and the usual quantity of boiling water the first action is the rapid extraction and neutralisation of the tannin by the soda present. The solution of tannin so obtained then immediately attacks the gelatin, which renders the tannin insoluble and inert. Thus the tanocea tablet exerts a distinct softening effect on the infusion, a muddy precipitate subsiding after a time. On adding the solution of a tanocea tablet to an ordinary clear decoction a precipitate of astringent principles is at once obtained, and the clear supernatant fluid will be found to be free from all bitterness and styptic property. The restorative and stimulating principle caffeine is not affected in any way by this process, nor is the agreeable flavour of the tea altered. It is the simplest, most effectual, and least objectionable method of removing from tea those astringent substances which are so frequently a source of discomfort to many who could otherwise drink tea with pleasure and advantage. We have tried this simple device in one or two cases where ordinary tea could not be taken without marked gastric disturbance, and the results have been very satisfactory. Since the tannin is thrown out of solution as soon as it is extracted, the leaves may be allowed to infuse for a much longer time, and thus the maximum amount of stimulating principle in the infusion is ensured.

VIFERA WINE.
(R. P. GEMMEL, 49, VIRGINIA-STREET, GLASGOW.)

Two kinds of wine have been received, one red and the other white, answering respectively to ordinary Burgundy and Chablis or white Burgundy. The results of analysis were as follows: Burgundy: extractives, 2·63 per cent.; mineral matter, 0·34 per cent., containing 0·6 per cent. of iron; sugar, 0·34 per cent.; tartaric acid, 0·33 per cent.; acetic acid, 0·12 per cent.; alcohol, by weight 11·62 per cent., by volume 14·37 per cent., equal to proof spirit 25·18 per cent. Chablis: extractives, 2·62 per cent.; mineral matter, 0·42 per cent., containing 0·48 per cent. of iron; sugar, 0·34 per cent.; tartaric acid, 0·47 per cent; acetic acid, 0·16 per cent.; alcohol, by weight 11·62 per cent., by volume 14·37 per cent., equal to proof spirit 25·18 per cent. From these results it is evident that the wines were in sound condition, free from the slightest excess of objectionable acidity (especially volatile acid). They are, however, decidedly heavy in character and full-bodied. For table purposes they are best diluted. There can be little doubt of their tonic character, iron being an important constituent of the mineral matter. Both are undoubtedly pure and natural products of the grape, possessing the vinous characteristics of the rich generous wines now sent to this country by our colonies.



EXT. RADICIS PERNIONIS.
(ARTHUR AND CO., 69, BERNERS-STREET, W.)

This is described as a new preparation for the treatment of chilblains, and is stated by its makers to be "the best application that has yet been known." It is also adapted, it is said, for the treatment of itching and bruises. It proves from the results of laboratory examination to be a spirituous extract of a well-known root. On diluting with water it turns turbid, but the turbidity is removed by ether, the ether yielding on evaporation an oily residue of peculiar smell.

A POLYMELIAN CANINE MONSTROSITY.

WE have received from the editor of *Our Dogs* the following account of a curious freak of nature occurring in a puppy which has recently been brought under his notice. The animal is a mongrel puppy, about six months old, belonging to Mr. Dewhurst, of Accrington, sired by a fox terrier dog out of an Irish terrier bitch. Although in fair condition it is rather smaller in size than a fox terrier puppy of the same age.

According to the description given by Mr. W. A. Taylor, F.R.C.V.S., in *Our Dogs*, the animal has a single complete head and male trunk, with limbs perfectly formed, whilst dependent from the lower portion of the right sternal region there is an extra pair of posterior limbs and a portion of pelvis. Both these legs possess, apparently, all the bones of the hind limbs as far as and inclusive of the femur; there is no hip-joint, as the pelvis is not entire, but there is a piece of floating bone which appears to be a part of the pubic portion. The skin and hair covering the extra limbs is continuous with that forming the

lower portion of the right wall of the chest, there being no bony union. Distinct arterial pulsation can be felt at the point of attachment. One of the most curious features in connexion with this extra portion is that it is, to quote Mr. Kipling, "a kind of a giddy harumfrodite," there being present evidences of both male—a rudimentary penis without a meatus—and female generative organs. There is also a constant dribbling of urine from the female urethra, clearly indicating either the presence of a kidney or kidneys or else a communication with the urinary apparatus of the body of the animal. There is no anal outlet or trace of coccygeal bones, the tail being represented by a small fold of skin.

As a freak of nature the animal will doubtless arouse a certain amount of interest, and it is to be hoped that, should death occur, the owner will allow some scientific expert to make a post-mortem examination in order that the result may be recorded.

THE LANCET.

LONDON: SATURDAY, AUGUST 28, 1897.

THE report to the Local Government Board on the preparation and storage of glycerinated calf vaccine lymph, drawn up by Sir R. THORNE THORNE and Dr. COPEMAN, constitutes an admirable supplement to the report of the Royal Commission on Vaccination. It will be in the minds of most of those who studied this latter report at all carefully that the general trend of the recommendations of the Commissioners was that every parent who desired it should have facilities for having his or her child vaccinated with calf lymph. There were, as Sir R. THORNE THORNE points out in his introductory letter to the President of the Local Government Board, "two points to which the Royal Commission gave prominence in their report. The first of these—one which the Commissioners put in 'the forefront'—is the recommendation in Section 437 of their report 'that parents should not be required to submit their children to vaccination by means of any but calf lymph.' The second, which is referred to in Section 448," is "that the addition of glycerine, whilst it leaves the efficacy of the lymph undiminished, or even increases it, tends to destroy other organisms."

For the last six or seven years Dr. MONCKTON COPEMAN has paid special attention to the subject of glycerination of calf vaccine lymph; indeed, it may be gathered that he was one of the first, if not the first, to put this method into actual practice; but so far from the method being generally adopted in this country, we learn from the report that Sir R. THORNE THORNE and Dr. COPEMAN had to go abroad—to Paris, Brussels, Berlin, Dresden, Cologne, and Geneva—in order that they might see the method worked on any extensive scale, and in order that statistics of results might be obtained that would be convincing to the lay minds of those in authority. It may be argued that we are a very "safe" people, both individually and collectively, and certainly if slowness and safety are convertible terms the argument may be sustained, for we find that most of the Governments and other authorities concerned in the countries visited by Sir R. THORNE THORNE and Dr. COPEMAN have since 1891, when Dr. COPEMAN announced the results of his experiments, been engaged on sustained and elaborate investigations into the best methods of preparing and storing glycerinated calf lymph. The result is that whilst we are paying attention to anti-vaccinationists and are occupying ourselves with refuting their arguments, Germany has perfected a system of vaccination in which arm-to-arm inoculation plays no part, and has succeeded in obtaining sufficient lymph from a single calf to vaccinate 6000 or even 15,000 individuals, we being, or having been, content to reserve sufficient lymph from every calf at the Local Government Board's animal vaccine establishment to vaccinate only 200 or 300 children.

It may possibly be suggested that this enormous dilution, or economising of the actual quantity of lymph, must lead to less efficient vaccination; but, as a matter of fact, what do we find is the case? Sir R. THORNE THORNE and Dr. COPEMAN brought a quantity of the most "dilute" lymph with them from Berlin, and at intervals of nine, eleven, and thirty-seven days after its collection made seventy-six vaccinations by five insertions in every case, with a mean insertion success of 92 per cent. With other samples of lymph, diluted with glycerine to only about one-third of the amount of the above sample, insertion successes were obtained in 97, 98, 99, and 100 per cent. when the lymph had not been preserved for more than thirty-one days.

It is now generally recognised abroad that the addition of considerable quantities of glycerine does not in any way interfere with the activity of the vaccine lymph taken from calves. Dr. COPEMAN, who demonstrated this fact some time ago, further pointed out that, curiously enough, the added glycerine exerts a distinct bactericidal effect on organisms that may by accident find their way from the skin of the calf to the lymph. Thus he showed that lymph taken with ordinary precautions often contained micro-organisms of various kinds, whilst the same lymph to which a certain proportion of glycerine had been added soon became entirely free from viable micro-organisms, as demonstrated by plate cultivations. Even the pus-forming organisms, which are fairly resistant to the action of most bactericidal agents, are killed by the glycerine which is added for the purpose of diluting the lymph. It has frequently been objected that under certain, no doubt remote, contingencies, tuberculosis might be transmitted from child to child or from calf to child. Glycerination of the lymph appears to remove the last fraction of danger on this score, as it has been experimentally proved that the tubercle bacillus, when added to a mixture of lymph and an aqueous solution of glycerine, rapidly loses its vitality. It appears, indeed, that glycerination of calf vaccine lymph should cause the disappearance of most of the objections now raised by those who are afraid to have their children vaccinated as a protection against small-pox.

What are the advantages of this glycerination of calf lymph? In the first place the amount of active lymph to be obtained from a single calf can be increased from twenty to fifty times, so that the difficulty of obtaining a supply of good lymph may be said to have been reduced to a minimum. It is frequently stated that calf lymph has, when inoculated into certain children, set up erysipelas, sometimes of a very grave form. The addition of the glycerine ensures the removal of any germs which might possibly produce erysipelas, suppurative changes, or, as we have already seen, tuberculous infection, the three conditions which are said to be possibly resultant from the use of calf vaccine lymph. Hitherto most people have preferred the vaccine taken from the arms of healthy children for the vaccination of their children, but for some time past there has been a rapidly increasing minority who have had a distinct preference for carefully collected and preserved calf lymph, and now that this marked improvement in the method of preservation has been adopted there can be no doubt that Sir R. THORNE THORNE's recommendation, that "vaccination, both primary and

Digitized by Google

secondary, carried out under the auspices of the Government, should be performed exclusively with vaccine lymph derived from the calf," will find favour in the eyes, not only of parents, but of medical practitioners also. One great advantage attending the addition of glycerine appears to be that the vaccine may be kept for a lengthened period in a moist form without losing its activity. In all probability the explanation of this rests, in part, at any rate, on the fact that putrefactive and fermentation germs are incapable of living and carrying on their special disintegration processes in the presence of glycerine, and the active vaccine agent is thus not destroyed. It is curious that the glycerine should exert so little effect on the vaccine if the active agent is of animal or vegetable origin, for, although under prolonged keeping the glycerinated lymph undoubtedly loses its activity, the falling off is so slow that no actual diminution of strength can be observed within a month or even longer, but at the end of three months a marked fall is observed, whilst in one instance the lymph had become inert in six months.

In their report Sir R. THORNE THORNE and Dr. COPEMAN go very fully into the whole question of the preparation of vaccine lymph as it is now carried out in the countries they visited, and what strikes the reader most forcibly is that vaccine establishments are no longer clean calf-houses; they are carefully thought out and well-equipped laboratories. In the report the calves are followed from the time they are purchased to the time they reach the butcher's table, where a careful examination is made for the presence of any tuberculous lesion in the carcase. Until this examination has been completed not a single tube of lymph is sent out for use. In some countries the animal is first tested with tuberculin; but in view of the above post-mortem examination the tuberculin test appears to be unnecessary, especially as its application involves a considerable amount of trouble and in some cases a certain loss of time. It should be stated, however, that the calves are usually kept isolated and under observation for about a fortnight before they are brought under treatment and are dieted most carefully, the diet varying of course in different countries. The various methods of cleansing the skin, of making the incisions or insertions, of collecting the lymph, of cleaning, emulsifying and glycerinating it are all given with a considerable amount of detail, and we are lead to expect that hairs and large epithelial particles similar to those that have been seen in samples of glycerinated lymph obtained in this country are in most cases removed by some contrivance or other. Details concerning the storage and distribution of lymph also occupy considerable space, but for these we refer those who take a special interest in the question to the report itself. It is interesting to note, however, that those who have had most experience of the preparation and action of glycerinated lymph are not by any means at one on some important, but perhaps minor, points. For example, some take the vaccine from the calf on the fifth day, others—and these appear to be in the majority—remove it on the sixth day from inoculation. Some, on the score of cleanliness, use cow calves only, others prefer bull calves, on the ground that the insertions on the skin of the scrotum give such good results. In Paris a certain number of patients are vaccinated directly from calf to arm, whilst in Germany and the other countries visited the lymph, before it is used, is always kept for some short time after the addition of the glycerine has been made. Centrifugalisation of the lymph has been tried in Berlin, but the nature of the results of this method of purification is as yet undecided. The lymph is undoubtedly of better appearance and contains fewer micro-organisms, even before the addition of the glycerine has taken place; but it is argued that if the active agent in vaccine virus is particulate and is locked up specially in the epithelial cells, continued centrifugalisation would remove it, and the lymph would lose its activity.

In the different laboratories very different proportions of glycerine are added. For example, in Paris the lymph is diluted with an equal bulk of glycerine; in Brussels twice the bulk of glycerine is added; whilst in Berlin fourteen parts of a solution of equal parts of glycerine and boiled water are added to one part of the epithelial pulp scraped from the vaccine vesicles. Some of the operators remove the vesicles by a single scraping movement, thus avoiding the collection of hairs and the admixture of blood with the epithelial mass and the fluid lymph, whilst others scrape the vesicles several times with the sharp spoon in order that they may remove as much as possible of the active material. These differences, however, are, after all, matters which can only be settled by direct experiment, and for their settlement well-equipped laboratories and expert workers are absolutely necessary. Such laboratories are now in full working order in most of the institutes visited, and much valuable work is being done in them, and we fully agree with Sir R. THORNE THORNE that laboratory accommodation with all the necessary appliances for the study of vaccine lymph should be added to the Local Government Board's animal vaccine establishment as soon as possible. A laboratory is now a necessary part of every hospital—there bacteriological and chemical investigations of various kinds are constantly being carried on for diagnostic purposes—and of every brewery and sugar refinery, where the purity and strength of beers, yeasts, and sugars have to be from time to time determined. How much more is such accommodation necessary for the examination of such material as vaccine lymph, which if not pure in every respect should never be used for purposes of inoculation? It has been due to the want of some means of testing and guaranteeing the purity of lymph that those who are opposed to vaccination have been enabled to make capital out of some of the objections that have from time to time been raised against it. The practical and statistical side of the vaccination question has been studied most carefully in this country, but much still remains to be done on the scientific side, especially from a bacteriological point of view, and we hope that the publication of the report now under consideration will cause those in authority to recognise the necessity of our being no longer dependent on the workers in other countries for the elucidation of problems already partially solved by our own workers. In the meantime we commend this report to the careful consideration of all who take an interest in the question of the preparation of good vaccine lymph.

THE Presidential Address delivered by Dr. SYMES to the Pharmaceutical Conference at Liverpool presents in a compendious form, not only a view of matters affecting the

Digitized by Google

interests of pharmacists at the present moment, but also of the progress which has been made in various directions since the foundation in 1863 of the institution under the auspices of which the address was delivered. The review is not less interesting than the view, and brings to light a very remarkable success, the result of corporate enterprise on the part of the pharmacists themselves, supported and supplemented by well-devised legislation. The great success of that period has undoubtedly been the perfecting of a system of dispensing drugs by the double process of reducing the manufacture to system and educating the dispensers to their work. For both these results the Pharmaceutical Society and the Pharmaceutical Conference are entitled to great credit each in its own way, although, of course, in a matter of this kind private enterprise, even although coöperative, could have accomplished little if it had not been reinforced by the strong arm of the law. The result is one upon which the great public have abundant reason to congratulate themselves, for it has enormously increased the success of the healing art, while the whole body of those who are engaged in the practice of that art—pharmacists, physicians, and others—to whom drugs are tools with which their daily work has to be accomplished, have special reason to rejoice in the circumstances which have brought those tools to their present perfection. It is difficult for the modern practitioner to imagine how disheartening must have been the working conditions of the good old days, when preparations were of no definite strength and purity was imperilled, not only by the unchecked abuse of adulteration, but also by legitimate differences of opinion as to formulas. That is now matter of history, and therapeutics has acquired the character of a science, because the materials with which it is conversant have assumed the exact nature of chemical compounds. Drugs, even though they remain physical mixtures of different materials, are not less susceptible of calculation and mathematical definition with reference to the purposes for which they are used than true chemical compounds themselves.

One-half of the gain resulting from this great advance in the art of compounding drugs would have been lost to the public if there had not proceeded *pari passu* with the improvement so introduced a corresponding improvement in the professional efficiency of the dispensers of them. A perfect tool is but an imperfect instrument in unskilled hands, and this work of education, even more perhaps than the work of standardising, is one upon which the Pharmaceutical Conference may congratulate itself. It is a work less easy to accomplish, and when accomplished more easily undone than the other. It pre-eminently needs the moral impulse which an annual conference can impart and the vigilant and authoritative criticism which a conclave of experts is alone competent to utter. The pharmacists have in this particular good reason to indulge in some professional pride. Not only has the standard of general and technical education within their ranks been raised with their coöperation during the past thirty years in a remarkable degree, but the material advantages of this change have accrued almost exclusively to the public. The pharmacist, far from rising in popular esteem in proportion to his increased merit, has simply dropped in that proportion out of the public eye. In any craft when technical education reaches a perfect result—that is to say, when the ordinary practitioner attains to finished skill in the use of his materials—the individual merges in the class. It is so in most of the mechanic arts; it is so in seamanship. TUBAL CAIN and PALINURUS would have no vogue in modern times. It is so with the pharmacist. The average standard is so high that within the limitations of the art it is difficult for anyone to be excellent in an eminent degree. There is in Dr. SYMES'S address some echo of a complaint that this is so; but it is precisely here that we hesitate to commit ourselves altogether to the view that he expounds. It is idle to repine at the want of recognition at the hands of the public, to which the most accomplished pharmacist must accustom himself, and not wise to construe it as a slight. It signifies only that the public reposes such complete confidence in the competency of the average pharmacist that it is not concerned to inquire who is more and who less accomplished. Such a frame of mind on the part of the universal patron shuts the door, no doubt, upon private ambitions; but no good citizen would desire to alarm the public out of its ungrateful security at the cost of exposing it to the dangers which alone could make it appreciate the trained pharmacist at his true value.

AT length the oracle has spoken. It is just half a century since, in 1847, the Poor-law Commissioners by a General Order provided in Article 99 that "any pauper of the fourth class whom the master may deem fit to perform any of the duties of a nurse or assistant to the matron may be so employed in the sick wards." Paupers of the fourth class were women "infirm through age or any other cause." Similarly, it was enacted that men "infirm through age or any other cause" might be employed in like manner as nurses in the males' sick wards. It was also enacted that the duties of a Poor-law nurse should be "to attend upon the sick placed under her charge and to carry out the orders of the medical officer in regard to their treatment." Until a few weeks ago these were the only orders or regulations issued by the Poor-law Commissioners or Local Government Board that had relation to the duties of a nurse. Many things have happened since then; nursing itself has developed into a profession, and the training that is necessary nowadays is of a very special kind. It is no longer left to SAIREY GAMP, but is a calling that exacts the devotion of a lifetime of educated and high-minded women. Nevertheless, the Local Government Board neither saw nor heard these things, and nothing was ever done to keep up with the times. It was left to a private philanthropic organisation, started by the efforts of Miss TWINING and a few other ladies seventeen years ago, to do a great deal that has been done in the way of improving workhouse nursing. They have done, it is true, very excellent work in the face of great difficulty, but it has always been by private influence, and not always with the concurrence of the guardians, who naturally look upon any outside agency with suspicion, that they have accomplished so much.

However, the Local Government Board has spoken at length, and though the Order dated Aug. 6th, 1897, which

Digitized by Google

is to be known as the Nursing in Workhouses Order, 1897, does not do all that it might, nevertheless, we have much to be thankful for, seeing that something has at length been done. Grave scandals have from time to time made their way into the public press, when patients have been scalded to death or otherwise neglected through the inadvertence and incompetence of the so-called "pauper help"—i.e., women infirm through age or any other cause. But we are glad to find that Article 99 of the Poor-law Commissioners' Order above referred to is by the new Order to be repealed, for Article 1 states distinctly: "Notwithstanding anything to the contrary contained in any of the Orders above referred to, no pauper inmate of the workhouse shall be employed to perform the duties of a nurse in the sick or lying-in wards of the workhouse or be otherwise employed in nursing any pauper in the workhouse who requires nursing." It also makes the very desirable regulation that even such pauper inmates as may be employed to do work in the sick or lying-in wards shall be subject to the approval of the medical officer of the workhouse. Article 2 enacts that persons employed as nurses or assistant nurses must have had proper training, such as "will render them fit to act in that capacity." In other words, it makes the employment of the trained nurse a necessity. A question, we fear, will arise out of this, for, if we are correctly informed, there exists considerable difficulty among some country guardians, who do not lay themselves out to make their officials particularly comfortable, in procuring the services of trained nurses. Much has hitherto been done to remedy this defect by the Working Infirmary Nurses' Association, which has, at the cost of considerably over £3000 collected by voluntary subscription, found suitable young women, and, if not sufficiently trained, has provided training for them for such situations. We learn from a report of the association that no fewer than 764 nurses have been thus supplied in the eighteen years during which it has been in existence. But we hear rumours that this admirable association has become so disheartened in its work as to actually entertain the idea of bringing its existence to a close. We sincerely trust it may not be so. But undoubtedly the question of providing trained nurses will have to be faced sooner or later. The demand for skilled nurses has so much increased of late years, the openings for them have become so much more numerous both in hospital and private work, that the supply, although it has increased, is not sufficient. The attractions of a country union are not very great, and the proverbial cheese-paring policy of the guardians prevents them from offering sufficient salary. It is not therefore surprising to hear that some country unions advertise repeatedly without obtaining any reply. What, then, is to be done to increase the supply? Some of the London infirmaries train their own nurses, and it seems to us that the sooner the authorities take the matter into their serious consideration the better. That the question should be faced either by the guardians in coöperation or by the Local Government Board as a State department would seem to be only reasonable.

Article 3 provides that where there is a staff of three or more nurses and assistant-nurses in a workhouse the guardians shall either appoint a superintendent nurse or, with the consent of the Local Government Board, direct that one of the nurses shall act as such. This, again, is a most desirable reform. One of the chief difficulties in the existing state of matters, and one which no doubt diminishes the supply of candidates in many instances, is that an untrained and sometimes an uneducated matron is placed in authority over skilled nurses. We do not think this ought to have so much weight as it is sometimes allowed to have, because the nurse should have no difficulty in getting on with her superior when she receives her orders practically from the medical man alone, and she ought to be able to act in harmony with those with whom she dwells. Often by displaying a little courtesy and deference friction may be avoided, and no institution can be governed by divided authority. The new Order, however, will help undoubtedly to diminish this friction. Finally, the new Order empowers the master, on the recommendation of the medical officer, to engage a temporary nurse in times of emergency. The Order, unfortunately, does not deal with the important question of the remuneration of nurses in workhouses, which, in our opinion, is hardly adequate considering the skill required and the various drawbacks to the situation, especially in provincial workhouses and infirmaries. Nevertheless, we heartily congratulate both the Local Government Board and the Poor-law service generally in obtaining at length a very important reform in workhouse nursing. In view of the fact that the metropolitan infirmaries alone contain some 13,000 sick persons, it is a question which affects the well-being of a very large section of the community, and it is naturally a question in which we take great interest, seeing that the Founder of THE LANCET initiated the great reform of 1847.

Annotations.

"Ne quid nimis."

"AN OVERCROWDED PROFESSION."

SUCH is the heading of a correspondence now appearing in the columns of the *Standard*, in which a poor account is given of the medical profession as a means of living on the twofold ground that it is overcrowded and that the immense growth of medical charity in recent years draws away the patients of medical men in ever-increasing numbers. "A Medical Man," who opens the correspondence, avers "that he is not far from the truth in stating that the average income of a medical man in the present day does not reach £250, and that this sum must be still further reduced should candidates continue to flock into the profession at the rate they have done in recent years." There are no very accessible data for the verification of this estimate. It is not seriously refuted by reference to the difficulty of filling up army vacancies. It is, perhaps, a little under the mark; but even so the compensation is a poor one for work so responsible and laborious, and representing an education so prolonged and costly. This correspondent is followed by another signing himself M.A., M.B., M.R.C.S., who enlarges on the way in which the hospitals are being invaded by classes of persons for whom they were never intended, in the belief that they will see a Fellow of the College of Physicians or Surgeons, but who oftener see the young resident physician or surgeon. In this way the private practitioner is robbed of his patients, the hospital physician is not

Digitized by Google

benefited, the patient is demoralised, and the charitable public are cheated. This correspondent endeavours to show how dearly the patients who go to hospitals pay in wasting time, incurring weariness, and having their cases often very cursorily treated. He quotes an instance of a mother taking two children to the waiting-room, all three suffering from diphtheria. It was alleged that on a recent hot day no fewer than sixteen patients fainted in one morning, yet the hospitals go on enlarging and ventilating their waiting-rooms and introducing amenities which invite the very classes that have no right to use them. The only plausible answer to such representations is of the sort given in the letter of "Mater," who had failed to get her child cured by private practitioners and was told that at the hospital they would soon make him well. In this way she justifies herself—presumably of the lower middle class—going to a hospital and getting a consultant's advice for the petty pence paid by out-patients at some hospitals. But the excuse is a poor one. No medical man wishes to exclude those who cannot pay a consultant and whose diseases are prolonged or difficult of treatment from the benefits of the hospitals. The contrary is the case—as the letter of "Audi Alteram Partem" shows. But "Mater" does specifically say that she could not afford a reasonable fee to a consultant. One great part of the remedy for hospital abuse lies in a better understanding on this subject between consultants and general practitioners. The writer who initiates the correspondence does so because the winter session of the various medical schools is rapidly approaching and by way of warning to intending students and their parents It does not admit of a doubt that the profession is overcrowded and that there is a growing disposition on the part of an ever-increasing section of the public to get medical attendance for nothing or on terms which in no way remunerate a professional man who has spent five or six years in medical education, to say nothing of the preliminary years spent in preparing himself for the medical schools. These facts have been demonstrated over and over again in the pages of THE LANCET and in the statistics of the General Medical Council and of the Metropolitan Hospital Sunday Fund. It is fit that they should be present to the mind of every young man who contemplates entering the medical profession. There is some reason to think that they are being pondered by those whom they concern, and it is to be hoped that they will be increasingly considered. It is too soon to despair of altering the social and economic facts on which half of the argument is based. The hospitals must be restored to the poor and restricted to such as cannot be treated properly at home, or they will suffer in public estimation and support. The physicians and surgeons whose skill makes them attractive surely will not persist in being parties to such a use of them as demoralises the public and injures the prospects of the men whom they educate. At the same time there is enough in these gloomy estimates of the profession as a calling to give pause to all who are not prepared to work hard in it, and so cope effectually with the competition of hospitals and low methods of practice. The proper form of medical attendance for all persons is the best private practitioner their means can command. There is a virtue in the continuity of the medical attendant. Such a relation has immense advantages which do not attach to stray interviews with a stranger at a hospital, and private practice is now conducted on terms almost too considerate to the poor and those of modest means. To men who realise the dignity of medical service and of the medical calling there is still room in our profession; but those who do not and who look for their reward in large incomes will do well to consider in the weeks which intervene between now and Oct. 1st the problems raised by the letters in our contemporary. We have written for the most part from the point of view of the medical student and practitioner. But the question of hospital abuse is a public one with wide bearings, involving fundamental ideas of charity and social morals.

"A PLEA FOR PUBLIC HEALTH."

IN connexion with the newspaper and other discussions regarding the Public Health (Scotland) Bill the *Scotsman* recently published a contributed article under the above title. Our attention was called to it only through a particularly feeble reply which appeared in another newspaper. Fortunately, the controversy in Scotland regarding the status of the medical officer of health is now in large measure settled by the amendments which were carried in the Report stage of the Bill in the House of Commons, but the article to which we refer is so good that we cannot refrain from quoting the latter part of it.

"In the nature of things ..... it is impossible to erect within the domain of public health two separate and independent departments. In local government there are many official spheres which are absolutely independent. The subject matter of their business is perfectly different. Their paths only cross occasionally, as those of every member of a civilised community must. Can there be a medical officer's and a sanitary inspector's departments in the sense that there is a town clerk's and a chief constable's? Can they act with no more 'relations' than the burgh engineer and the inspector of cleansing? It is obviously impossible. The sanitary department is as much an administrative unit as the department of town clerk or burgh surveyor. Writing of municipal government Dr. Bryce says[1]: 'Americans are sufficiently adept in the administration of large business enterprises to understand that in any such undertaking some one man must be given the power of direction and the choice of his chief assistants; they understand that power and responsibility must go together from the top to the bottom of every successful business organisation.' Unfortunately in Scotland it has hitherto been supposed either that the administration of public health falls naturally into two independent businesses, or that, being one large business enterprise, it could yet be successfully prosecuted under two responsible heads. We have shown that the former supposition is incorrect. Our legislators seem to imagine that alone of all businesses that of public health administration can prosper under conditions which in the abstract are inconsistent with prosperity. 'Can two walk together except they be agreed?' In the course of the discussion of this Bill it has become apparent, if it never has been so before, that medical officers and sanitary inspectors are not agreed. Let the inference be drawn that they do not walk together. It is no fault of theirs. Indeed, it shows a great deal of forbearance and self-restraint somewhere that no glaring public scandal has so far arisen. But there is daily friction and daily injury to current business, and daily loss to progress in sanitary knowledge. The sanitary inspector may go on removing 'nuisances' for ever, registering them in folios, and summing up their number in billions, but if he is independent of the medical officer their influence on disease will never be discovered. The medical officer may study the returns of deaths provided for him by this Bill until he is grey, and laboriously tabulate their nosology, but he might almost as usefully classify the flora of his district unless he can at the same time direct the investigation of the 'nuisances' related thereto. You place those officials in a false position and you are astonished if they disagree, and you believe that, disagreeing, their common work is still well done. In the present Bill you place them in a more false and impossible position than ever. So far as a statute can do such a thing, you give equal value to the opinion of these officials on questions of injury to health. How this will work out in courts of law it is easy to foresee. Ninety-nine per cent. of the 'nuisances' are removed for the asking, and in the larger burghs are never even seen by the statutory official. Anybody can see them and might sign the document which advises their 'author' of their existence. The signature of the subordinate who inspects and sees would be quite as efficient as that of the statutory sanitary inspector which may be affixed by a mechanical stamp. The case is exactly the same

[1] American Commonwealth, first edition, vol. ii., p. 303.

Digitized by Google

as that of the medical officer in the removal of cases of infectious disease and carrying out of disinfection. At one time warrants were frequently required. Now seldom or never. It would be quite as reasonable, and, in fact, be the true logical sequence of authorising the sanitary inspector to certify injury to health in the one per cent. of cases of nuisance which require resort to legal process for removal, to authorise him to inspect and certify for compulsory removal or disinfection the moiety of cases of infectious disease in which removal to hospital or disinfection are resisted. It is vain to assert any necessity of administration in some counties to justify such departures from principle. No local authority has ever said such a necessity exists. There is no evidence whatever of its existence. On the contrary, there can be no local peculiarity to which competent organisation is unable to adapt a sound principle."

The article was reprinted in full from the *Scotsman* and issued to Members of Parliament. A few copies remain, and can probably be obtained by our readers from the secretary of the Society of Medical Officers of Health for Scotland, Dr. Maxwell Ross, Avenel, Maxwelltown, Dumfries.

FIRST-AID FOR SAILORS.

OF the value of ambulance lectures there can be no two opinions. They enable men who are otherwise untrained to afford assistance to the injured during the interval between the occurrence of the accident and the appearance of a medical man on the scene. In hæmorrhage a minute may be of the utmost importance, and in fractures first-aid is of great utility, as the popular method of diagnosing a fractured leg is by seeing if the patient can walk. Though all must acknowledge the great value of first-aid, yet it is very necessary that those who have undergone this instruction should not take upon themselves to treat conditions which are beyond their skill. A letter appeared in the *Morning Post* of Aug. 14th urging the importance of first-aid lectures being given to the officers and men of the merchant service. With this we fully agree, but we cannot help thinking that the instance which was put forward in that letter as an example of a case in which first-aid would have been of value was hardly one which would have been likely to benefit by such treatment. One of the officers of the ill-fated steamship *Aden* had his shoulder dislocated, and it was not reduced until a fortnight later. Most lectures on first-aid hardly do more than mention dislocations, and the volume, "First-Aid to the Injured," issued by the St. John Ambulance Association, distinctly and properly says: "No one but a medical man should attempt to reduce or replace a dislocation, as this operation requires a very great amount of technical knowledge."

THE DANGERS OF ARTIFICIAL RESPIRATION.

THE most obvious thing to do when a patient fails to take air into his lungs while he is under the influence of an anæsthetic is to adopt one or another form of artificial respiration. In most cases the treatment is a correct one, and leads to a successful recovery of the patient. It must not, however, be assumed that in every case in which the breathing stops artificial respiration is the first act to be performed or is it a proceeding free from danger. In more than one instance resort to this method has led to fracture of the ribs owing to some excited assistant pressing too vigorously upon degenerate bones. There must in every case be a cogent reason for trying to force air into the chest and a clear knowledge that at the same time no impediment exists in the upper air passages to its free entrance and exit. There have been numerous cases in which foreign bodies—balls of worsted, artificial teeth, and masses of undigested food—have become engaged in the air passages, and have only been discovered after futile efforts at artificial respiration had been abandoned, as they had failed in their object. Not infrequently when abdominal section has to be performed to relieve intestinal obstruction there is a fatal tendency for the stercoraceous vomit so liable to occur during the operation to get sucked back into the larynx. This is the great peril of the anæsthesia in such cases, and every instance of death under it is a warning. Through the courtesy of Mr. W. F. Cholmeley, the house surgeon of the Wolverhampton and South Staffordshire Hospital, Wolverhampton, we are able to give the particulars of a case which illustrates this point, although we have no doubt that the actual performance of artificial respiration was indicated in this particular case. It appears that a man, aged fifty-eight years, exhausted by disease, was to be operated upon to relieve obstruction, caused, as was found at the necropsy, by annular carcinomatous growth constricting the intestine at the ileo-cæcal valve. The general condition of the patient was very bad, and the operation had to be delayed by the patient's refusal to give his consent, so that at the time he was given the anæsthetic his state was a grave one. He took the ether well. What degree of anæsthesia was obtained we are not told. In ten minutes, the abdomen being opened and the surgeon being engaged in handling the intestines to discover where the constriction was, the patient commenced to vomit. He became livid and a gurgling was heard in his trachea. Artificial respiration was resorted to for a short time without improving the man's condition, and then tracheotomy was rapidly performed. A quantity of stercoraceous vomit issued from the tracheal tube, and although the artificial respiration was kept up the man died. There can be no doubt that in cases where it is certain that vomit has entered the lungs the first thing to do is, as was done in the present case, to perform tracheotomy and draw out with some pump all the fluid which can be got from the air-passages. Artificial respiration when done by pressing upon the ribs and moving the arms can only force the stercoraceous vomit into the finer bronchi and effectually cut off any chance of the patient's recovery. It has been suggested that preliminary washing out of the stomach lessens the risk of vomiting, but it is not at present certain how far this can be relied on as a safeguard, since, as the stomach is emptied, a renewed regurgitation from the intestines is liable to occur. It seems probable that the inevitable manipulation of the intestines induces the reversed peristalsis which culminates in vomiting. Were this danger considered imminent it might justify a preliminary opening of the trachea and plugging above the tracheotomy tube, so as to effectually shut it off from the pharyngeal space. Whether such a procedure would increase too much the peril of the case experience alone can decide.

MINERAL WATERS AND MUDS OF RUSSIA.

VISITORS to Russia for the International Medical Congress will have the opportunity of visiting some of the interesting Caucasus spas. Considering the immense size of Russia it is only natural that she should possess an extraordinary number and variety of mineral waters. Dr. Frank G. Clemow's English pamphlet on "The Medicinal Waters and Muds of Russia"[1] comes in good time, and is of great interest even if English medical men, or their French and German colleagues, are not likely at present to send many patients to Russian spas. Three hundred mineral water springs and muds have been already examined and described in Russia, but others are known to exist, and when railways have opened up the vast Russian empire, it is to be expected that some out of the many Russian spas will become as famous and as much visited as the well-known health resorts in Central Europe. Moreover, balneology and balneo-therapeutics are being much studied

[1] St. Petersburg, 1897.

Digitized by Google

in Russia; balneological societies have been formed in the Caucasus and at Odessa, there are professors of balneology in the principal Russian universities and in the St. Petersburg Army Medical Academy, and the Caucasus springs have been placed under the control of a separate State department. The assistance of French engineers, who had made a speciality of mineral water springs, was obtained in dealing with some of the Caucasus sources, and a school of similar engineers has already sprung up in Russia itself. The Caucasian mineral waters may be divided into four chief groups: (1) the thermal sulphurous waters of the neighbourhood of Piatigorsk, with the Maria Theresa spring not far distant, a bitter aperient water; (2) the thermal iron-containing waters of Jeleznovodsk; (3) the muriated alkaline waters of the Essentuki group, of which the best-known (No. 17) spring, according to the most recent analysis, contains 4·3 parts carbonate of sodium and 3·6 parts common salt per 1000 (the dried salts from this spring are sold in different parts of Russia); the Essentuki sulphurous alkaline waters are used for baths; and (4) the cold, weakly mineralised Narzan spring and other springs near Kislovodsk, used both internally and externally. Besides all these waters there are excellent alkaline springs at Borjom, resembling some of the less thermal springs of Vichy. The salt lakes or brine pans on the northern shore of the Black sea, especially near Odessa and in the Crimea, furnish abundance of strong common salt waters; from the bottom and neighbourhood of these lakes ("limans") the mud for the already well-known mud baths of Odessa is obtained. Besides the salt mud baths, as used at Odessa and in the Crimea, a dilute kind of mud bath is used at Piatigorsk in the Caucasus, Hapsal in Esthonia on the Baltic coast, and at other places. A third kind of mud bath, or rather a peat bath, resembling the famous peat baths of Franzensbad in Bohemia, is employed at Lipetsk, in the south-central government of Tambof. Finally, as curiosities, come the very hot springs of Goriatchevodsk, Bragoun and Kalvadjar in the Caucasus, and of Banauin and Karkin, some of which are at boiling point, but they are equalled by the Great Geyser in Iceland, the waters of which have been ascertained to reach 212° F., and at ten metres below the surface even 219° F.

A FALSE MEDICAL CERTIFICATE.

IT is gratifying to find the Registrar-General showing due vigilance in the prosecution of offenders under the Registration Acts. On the 17th inst. at the North London Police Court, Mr. S. Kent Jones, medical assistant, unqualified, was summoned for making a false certificate of the cause of death of a child, Flora Stone Mack, contrary to the provisions of the Births and Deaths Registration Act, 1894, Section 40. The offence happened in this wise. Mr. Jones was acting as the assistant of Mr. Isaac Cohen, 151, Blackstock-road, N., who was absent for a holiday. The defendant's instructions, according to the report in the *Islington Gazette*, were curious. He was to sign "ordinary certificates for black eyes, injured fingers, and the like," but in the event of more serious cases he was to call in a medical man who was named. When the serious case arrived the medical man named had gone away and left no one in his place. The defendant was "horrified" at the situation in which he found himself, but "to save the trouble of an inquest and a post-mortem examination to the parents" he signed a certificate of death from pneumonia. The certificate was signed neither in the name of the defendant nor in that of his principal, but as "J. Cohen." As Mr. Cohen always signed "Isaac Cohen" the fraud was detected. The facts were elicited with great clearness by Mr. Charles Townley, Superintendent Registrar of Islington, who prosecuted, and they did not admit of dispute. The solicitor for the defendant admitted them at once and relied on the evidence of previous good character, which, however, as both Mr. Townley and the presiding magistrate, Mr. D'Eyncourt, argued, made his error worse in a sense, seeing that he should have known better. It is much to be regretted that there was no necropsy and no medical evidence; in such cases the fullest information should be obtained. In the end Mr. D'Eyncourt, recognising the gravity of such offences, inflicted the full penalty of £10 with Treasury costs of £1 16*s.* 6*d.*, or one month's imprisonment. The case is one of much public importance. It is amazing, in the light of all that has been done to discourage the employment of unqualified assistants, that Mr. Cohen should go away and leave the greater number of his patients in charge of such a person. It is not to be supposed that he authorised his assistant to use a false name or to sign death certificates, but he authorised him to sign other certificates and he placed him in the responsible position of a locum tenens. Mr. Townley said that doubtless such action would be dealt with by the General Medical Council. It is for the Registrar-General and the Council respectively to do their part and to protect the public from unqualified practice as far as their powers enable them to do so.

"EYELID SYMPTOMS IN GRAVES'S DISEASE."

IN a recent number of the *Edinburgh Medical Journal* Mr. Arthur Maude has published an interesting and suggestive paper on this subject. The two chief abnormal variations in movements of the eyelid are von Graefe's sign—the eyelid descending not synchronously with the descending globe, but more slowly and it may be more jerkily, and Stellwag's sign, consisting in retraction of lids and consequent increase in the width of the palpebral fissure. This retraction is most obvious in the upper lids and is frequently associated, as is seen when the patient's gaze is directed downwards, with a cupping of the lower lid. Both these signs are quite independent of exophthalmos, and their clinical value is difficult to estimate. They are neither constant nor pathognomonic, and are variable even in the same individual. Von Graefe ascribed the deranged movement to spasm of the fibres of Müller. More recently Ferri has advanced the theory that the retraction of the lid is the result of the mechanical shortening of the levator palpebræ due to the increased volume of blood-vessels distributed in its substance. Mr. Maude is of opinion that such an explanation might be true in a few outstanding cases, but could scarcely be so in all. Two theories are open as an explanation—viz., that the conditions are due to spasm of the raising muscles or to paresis of the orbicularis. That irritation of the sympathetic can produce retraction of the lids was shown by Remak's experiment and is further demonstrated by the action of cocaine as an irritant of the terminations of the sympathetic. Two difficulties present themselves with regard to accepting irritation of the sympathetic as an explanation, first, that this irritation does not affect the iris or ciliary muscle, both of which react very readily to external stimuli, and secondly, that the phenomena of retraction of the lid and impaired movement, although often variable, may be constant for long periods—a condition scarcely likely to be the result of irritation. On the other hand, it is stated that there is direct evidence that paresis of the orbicularis and other upper facial muscles is almost constant in Graves's disease. This group of muscles as regards its nervous supply is closely connected with the oculo-motor nucleus, and it would thus seem that the eyelid symptoms in this disease are intimately associated with changes in the third nerve nucleus. Mr. Maude's paper, it will be seen, gives an interesting and comprehensive statement of the

Digitized by Google

varying explanations offered in reference to the movements of the eyelids, and he himself evidently leans to the last-mentioned theory—viz., an affection of the oculo-motor nucleus and a consequent paresis of the upper facial group of muscles. But it might be objected to such an explanation that if, as is stated, this group of muscles is almost constantly weak, the movements of the lids should also be constant, and, as is well known, this is by no means the case, so that perhaps a satisfactory explanation for all cases is not yet forthcoming.

HOSPITALS FOR SOUTH LONDON.

ONE practical remedy for the want of hospital accommodation in South London is to get rid of hospital abuse and reserve St. Thomas's Hospital and Guy's Hospital severely for the really poor and for fit cases, instead of catering for the well-to-do. The proposals to transfer hospitals on the north side to the south side of the river sound slightly impracticable. The managers of all our hospitals are gratuitously undertaking the impossible task of catering for huge classes who can well take care of themselves and for whom the charitable public will not much longer feel it their duty to provide.

A NEW METHOD OF STUDYING THE PATHOLOGY OF THE VERMIFORM APPENDIX.

THOUGH the number of cases in which the appendix vermiformis has been removed is undoubtedly very large, but little work has been done in investigating the exact conditions present in the appendix. Dr. R Abbe, of New York, published a paper in the *Medical Record* of July 10th, in which he showed that, by distending the appendix with 95 per cent. alcohol and then immersing the organ in alcohol of the same strength, the pathology could be investigated much more satisfactorily than by the ordinary methods. The illustrations which accompany the paper show the chief types which are met with, and the differences, which are great, must be of importance in the pathology. The method is obviously of great value, and the results obtained should be of practical value in treatment.

ANOTHER DEATH FROM ANTHRAX.

AT an inquiry held at Bradford on Aug. 11th, regarding the death of a woman who had been engaged in wool-sorting, some interesting facts were brought to light concerning the way in which the new wool-sorting regulations are carried out, or rather set on one side. The medical officer of health of the district is of opinion that the case was one of anthrax, and, taking into consideration the circumstances under which the death occurred and the fact that a microscopical examination of the blood was made, there appears to be little doubt as regards the diagnosis. Although the infection was probably through the respiratory passages it seems that this woman was allowed to go to work whilst wearing bandages rendered necessary by the infliction of a wound on the arm. The dust from the dust chambers removed once a week should by the regulations laid down be burnt, but it is alleged that it was given away for the purpose of being transformed into an artificial fertiliser or manure. It seems incredible that people should think of using such a material for land. It was urged that disinfectants were sprinkled over the floors of the rooms in which the wool-sorters were working. It seems absurd with our present knowledge of the resisting power of anthrax spores to play with them in this fashion. Nothing but the most careful disinfection can be of the slightest value, and the mere sprinkling of disinfectants simply leads to a false sense of security and to the neglect of real precautions. What with the minimising of the draught, the contracting of the flues, the irregularities as regards opening bales in rooms not specially set apart for the purpose, and similar breaches of regulations, the astonishing thing is that fallen Persian wool, even when greasy, does not give rise to more cases of anthrax than are at present attributed to it. The manufacturers may complain that the restrictions put upon their trade interfere with the rapidity of work and therefore with their chance of competing in the open market; but as the various questions bearing on wool-sorter's disease are now no longer debatable it is surely time that an effort should be made to compel compliance with the new regulations, which, good as they are, in many respects might still with advantage be made more strict. Until, however, an effort is made to enforce even the present regulations we must expect from time to time a recurrence of these sad cases of death from anthrax.

UNQUALIFIED PRACTITIONERS AND DEATH CERTIFICATES.

WE publish in another column the account of an inquest held on Aug. 5th at Rosedale Abbey, Pickering, Yorkshire. As will be seen by the evidence the deceased, a woman aged fifty-six years, was under the treatment of an unqualified practitioner. The latter gave a certificate that death was due to "inflammation of the bladder and peritonitis." The registrar refused to accept the certificate on the grounds that it was not signed by a legally qualified medical man and that the death was sudden. On the case being reported to the coroner he decided to hold an inquest, and issued an order for a post-mortem examination. The necropsy revealed acute inflammation of the kidneys. The bladder was empty and contracted and free from disease. There was no peritonitis. What was in reality suppression of urine had been regarded as retention. It seems strange on the diagnosis that a catheter was not passed. What symptoms there could have been to suggest cystitis we are at a loss to understand. Even qualified medical men are liable to err, since medicine is not an exact science, but with the facts before them it is astonishing to a degree that the jury should for one moment have unfavourably criticised the registrar's action in refusing to register the death. It might have been thought that they would have expressed and recorded their approval of the course he took, instead of condemning both him and the coroner in the rider to their verdict that "the post-mortem examination and the inquest were unnecessary." We consider the case was eminently one for the fullest inquiry.

MATERNITY CHARITIES AND UNMARRIED WOMEN.

AN attempt to define the normal relation between childbirth and the work of charitable relief might at first sight appear to be superfluous. Yet the fact remains that such a definition is still unknown, or if it does exist is too imperfectly understood to command general approval. Where the antecedents to matrimony have been quite regular there is of course no difficulty save that of the expense incurred. The case of illegitimate childbirth on the other hand is quite different. Questions of moral responsibility have entered in here, and the consequence is that public institutions which freely accept as inmates poor and deserving married women have no offer of help for a maiden mother. While we are willing to spare by every due consideration the feelings of the former class with regard to social surroundings, we cannot but think that the distinction in treatment so favourable to them is unduly neglectful of their erring sisters. It cannot be defended on the ground of charity, unless we accept the much wider proposition that every mischance of illness which is the direct outcome of a vicious

Digitized by Google

practice is outside the province of the charitable healer. The close connexion between illegitimacy, concealment of birth, and infanticide needs no explanation. Such preventive measures as have hitherto been employed to destroy this mischievous and criminal combination have not been highly successful. The question remains whether they should not be supplemented by such public and charitable aid as is plainly needful to secure the safety of mother and child at the time of birth. We would answer this question in the affirmative. Mr. Frederick Lowndes, in a paper recently reprinted, advocates a similar view. He proposes that midwives attached to maternity hospitals should be eligible for attendance on cases of labour without distinction outside the walls of these hospitals, and that provision should be made for the reception of a certain number of necessitous cases within the wards also. We believe that the adoption of these or similar suggestions would neither, in a well-regulated institution, tend to lower our present standard of morality nor act upon the recipients of charity as an encouragement to do evil. A judicious selection of cases for admission would of course be imperative, and a preference, though not wholly exclusive, would naturally be given to married women. Defended by such needful safeguards, the arrangement suggested should, we consider, work well and should prove in the end to be both a humane and a politic measure.

THE OPERATIVE TREATMENT OF SPINAL CURVATURE.

AT the French Academy of Medicine M. Chipault has from the commencement of his researches on the reduction or correction of spinal deviations maintained that the correction will not be permanent unless the vertebral column is kept in its new position by direct fixation of the spinous processes; this applies both to scolioses and to the results of Pott's disease. All the authorities on the subject now agree with him. M. Regnault has, in the first place, demonstrated before the Anatomical Society that Pott's disease and spinal curvatures (scolioses) if left to themselves tend to recovery by ankylosis of the posterior portions of the vertebræ, and that metallic fixation of the processes consequently does no more than anticipate in a most logical way the natural process of recovery. In the next place, M. Ménard has exhibited to the Academy and to the Surgical Society a series of anatomical preparations which proves the harmlessness of the operation for reduction. So far as the spinal cord and the parts surrounding the vertebral column are concerned, the correction of these deviations sometimes produces a remarkable change in the configuration and dimensions of the space lying in front of the vertebral column, and these anatomical preparations show that for the purpose of rendering the improvement permanent it is necessary that the spine shall be fixed in the new position. Many cases of recent occurrence in which distortion returned when fixation was neglected after correction of the deformity prove the absolute necessity for fixation of the processes. The attention of surgeons in many different places seems at the present time to be directed to this subject, and M. Chipault has now given an account of the improvements which he has during the last few months made in the operation originally devised by him. It consisted, as will be remembered, in tying the processes with stout silver wire, a method which is satisfactory and will continue to be employed under certain circumstances, but is nevertheless sometimes difficult of application on account of the stiffness of the wire. In place of the wire he therefore now uses hooks of four different forms, two for lateral deviations and two for antero-posterior deviations; each form of hook is made in two qualities, one being rigid, for use when it has been possible to correct the distortion completely, and the other being pliable, so as to be available when the correction of the deviation is only partial. The hooks can be applied with the utmost ease. They cause no local disturbance and do not interfere with the development of the portion of the spine to which they are applied.

A PATIENT FINED FOR LEAVING A HOSPITAL.

A PATIENT has lately been fined for leaving a fever hospital while suffering from typhoid fever. He had been an inmate for some time and had apparently been very ill, but during his convalescence he thought he was well enough to go and so walked out one day without saying anything to anyone. Patients in general hospitals not infrequently practise this mode of departure, which probably does little harm to anyone except the patient himself; but in the case of infectious hospitals things are different, for unless the patient and his clothes are properly disinfected disease may be spread to any extent. It is thus right that patients should understand that although they may risk doing harm to themselves by leaving hospitals against advice, they must not be allowed to convey infectious diseases to other people who are unfortunate enough to come in contact with them.

THE FAMINE IN INDIA.

THE news from the famine districts of India has been so uniformly good for some weeks that we hope we are now within a measurable distance of the ending of the acute stage. But before the famine passes out of men's minds or is crowded out by the more exciting news of frontier wars, it may be well to recall the chief causes of the scarcity of food in the famine-stricken districts. No rain, no food for cattle, then starvation of the earth and its dwellers. Cattle are fed during the year for three months corresponding to the rainy season upon green grass, and then for the next four months they are fed upon hay made from this same grass; but at the end of seven months the supply is exhausted, and for five months the animals get only millet stalks as their staple food. It must be remembered that beans, barley, and oats grow only in Upper India. When the supply of rain is abnormally diminished the grass and hay are deficient, and the cattle die for want of food. The dearth of cattle puts an end to all bullock traffic, to the carting of grain for human needs, to ploughing, and to all agricultural work. Ploughing in India is done twice a year and is impossible except after the rains, because the ground at other times is too hard and fissured. In the old days the natives used to bury grain for years, and so in famine times there was a hidden store of food for men and cattle, but to-day the grain is all exported by rail to Bombay, and thence out of India. This is a necessary sequence of the modern extension of railways throughout country districts.

POLYNEURITIS.

AT the recent meeting at Baden Baden of the South-west German Society of Neurologists and Alienists[1] Professor Strumpell directed attention to some points in the symptomatology of this disease. He mentioned in particular the occurrence of double facial palsy in alcoholic neuritis as a result of an affection of both facial nerves. This condition he had observed on two occasions. He also referred to a hitherto undescribed affection of the auditory nerves which had been described by Professor Kiesselbach—viz., true nerve deafness on each side—passing off in three weeks, and being replaced by noises

[1] Neurologisches Centralblatt, p. 610.

Digitized by Google

in the ears lasting for a long time, the result, doubtless, of neuritis of the auditory nerve. He also referred to the frequent occurrence of psychical disturbances in this disease, and especially the difficulty experienced by the patients in retaining in the memory any fresh impressions. The patient referred to as suffering from nerve-deafness was unable to recall words repeated to her or objects shown to her after the lapse of a quarter of an hour. Anatomically the conditions found in alcoholic polyneuritis consisted in slight changes in the anterior horn cells, profound degeneration in the peripheral nerves, and very slight changes in the muscles in spite of complete reaction of degeneration. Professor Strumpell expresses the opinion that the anatomical conditions underlying this phenomenon of degenerative reaction still require investigation.

THE INTERNATIONAL JOURNAL "JANUS" AND EPIDEMIOLOGY.

THAT enterprising journal, *Janus*, which we commented upon in our issue of Jan. 9th, 1897, is anxious to bring about an international system of reporting epidemiological data, and thus to give warning of epidemic storms in somewhat the same way that atmospheric disturbances are now heralded so that precautionary measures may be taken. To quote the words of the editor:—

"In furtherance of these aims we purpose giving, as soon as arrangements can be made, a bi-monthly record of the progress of epidemiology, which shall include—(*a*) current statistics of the morbidity and mortality from epidemic diseases—contagious, miasmatic, and miasmatic-contagious—from states, provinces, and cities for which such data are available, accompanied when possible by the meteorology; (*b*) original observations on epidemic diseases; (*c*) historical records of epidemics in particular countries and cities, and their periods of prevalence and quiescence; (*d*) special communications on subjects of epidemiological interest. We shall feel deeply indebted to any of the collaborateurs or readers of *Janus* who will undertake to furnish accounts of epidemic diseases in their respective countries, or who will regularly supply copies of official bulletins of morbidity and mortality relating to the districts in which they reside which might otherwise be inaccessible to the Rédaction, or who may be disposed to assist us in any other way. Communications on this subject, in English, French, German, or Italian, to be addressed to Dr. A. Davidson, 30, Morningside-drive, Edinburgh."

We can only wish the editor of *Janus* every success in his project—one which we think is very valuable, but at the same time very difficult to carry out.

MEDICAL EXAMINATION OF CANDIDATES FOR THE ARMY.

SOME correspondence has recently taken place in the columns of the daily press relative to the system in force for the physical examination of candidates for Woolwich. It appears that a boy who went up straight from Cheltenham College passed in first at the last competitive examination for the Royal Military Academy, and was a few days afterwards rejected as medically unfit for the service. It is needless to say that this involved a great waste of time, work, and money, and that the result must have been a very keen disappointment to the boy, his family, and all concerned. It is impossible not to sympathise with them. The competition for commissions in the army is very severe and the standard for Woolwich is very high, and the wasted effort, when it is wasted, is consequently a really serious matter. A communication signed "H. C. D.," which subsequently appeared in the *Times*, contains some sensible comments, and puts the case fairly. It points out that the medical and physical requirements are very clearly set forth in the published official regulations on the subject, which can be obtained through any bookseller, and that if the parents or guardians of the intending candidate would only procure a copy of these regulations and take them and the boy to any careful and competent medical practitioner in order to see whether he fulfilled all the conditions laid down before commencing the requisite course of study and training, much, if not all, of this great disappointment would be saved. It is, nevertheless, pointed out that practically a preliminary examination might be made available for candidates at the hands of the Army Medical Staff by making use of the existing machinery at the headquarters of district commands and regimental districts where there are qualified medical officers with the necessary experience and the test appliances required for the examination of army recruits. Such a preliminary examination, which could, of course, only deal with existing conditions and states of health, would, at any rate in many cases, obviate the bitter disappointment of wasted effort.

PERFORATION OF A GASTRIC ULCER INTO THE PERICARDIUM.

THE probability of a gastric ulcer perforating the wall of the stomach depends chiefly on its situation. An ulcer on the anterior surface of the stomach will almost certainly lead to perforation if the ulcerative process continues; but should the ulcer be situated on the posterior wall adhesions form very readily, so that the stomach becomes adherent to the diaphragm or to the left lobe of the liver; but the diaphragm itself may become perforated by an extension of the ulceration, and then the ulcer may open into the left pleural cavity or into the pericardium. Perforation of the diaphragm by a gastric ulcer is decidedly a rare occurrence, and even when it does occur the pleura is much more frequently affected than the pericardium. Of twenty-eight cases of perforation of the diaphragm by gastric ulcers collected by Ludwig Pick[1] only ten were cases in which the ulceration had perforated the pericardium. In THE LANCET of Aug. 14th we recorded a very interesting case which occurred in the practice of Mr. Collingwood Fenwick, in which a gastric ulcer had perforated the pericardium with an immediately fatal result, and yet no previous symptoms had occurred to point to the presence of the gastric ulcer. In four of the ten cases collected by Pick the two surfaces of the pericardium had become adherent before the ulceration had perforated, so that the ulcerative process involved the substance of the heart itself.

WE regret to announce that Sir Joseph Désiré Tholozan died at Teheran (Persia) on July 30th in his seventy-seventh year. Sir Joseph Tholozan had held the appointment of physician to the Shah since 1858. He was a Commander of the Legion of Honour, a corresponding member of the Institut de France, and an Honorary K.C.M.G.; various orders and decorations were also conferred on him by the Persian, Russian, and Italian Governments.

PROFESSOR CORFIELD has been elected an honorary member of the Royal Society of Public Health of Belgium, of which he has been a corresponding member for some years. The honorary members consist of Ministers, Ambassadors, and other high State officials, and a few foreign hygienists. Professor Corfield is the only Englishman who has received this honour.

THE Queen has been pleased to appoint Mr. Henry Edgar William Hoffmeister, M.R.C.S. Eng., L.R.C.P. Lond., Surgeon

[1] Zeitschrift für Klinische Medicin, vol. xxvi., p. 473.

Apothecary to Her Majesty at Osborne, jointly with Mr. William Hoffmeister, M.D. Heidelb., and Mr. John Bates Hoffmeister, M.R.C.S. Eng., L.R.C.P. Edin.

THE vestry of St. James's, Westminster, have contributed £100 to the Middlesex Hospital and £150 to the Prince of Wales's Hospital Fund out of the surplus profit derived from the grand stand erected in Waterloo-place to view the Jubilee procession.

MR. W. ERNEST THOMSON, M.A., M.D. Edin., has been appointed to the chair of Physiology at Anderson's College, Glasgow, in room of Dr. Campbell Black.

THE BRITISH ASSOCIATION AT TORONTO.

IT would seem as though the members of the British Association this year had conspired together to make the scientific proceedings at their annual meeting at Toronto of more interest than usual. If so, the conspiracy has succeeded, for a more interesting and a more comprehensive list of subjects for the opening addresses could hardly have been selected. And many of them possess a special interest for medical men, since though, of course, each subject was dealt with in its proper section, yet many of them were related very closely to the science which concerns our readers most. The presidential address was delivered by Sir John Evans, K.C.B., who, though leaning naturally enough to the consideration of archæology as a science, did not forget to generalise so as to include in his discourse pertinent references to the progress of geology, palæontology, chemistry, and the allied sciences, chiefly in their bearing upon the history of man and of the world. How far Sir John Evans succeeded in his task of delivering an address on science in general our readers will be able to judge for themselves, as we print the address in full this week.

At first sight it is not apparent why Professor Michael Foster took for the theme of his address to the Physiological Section the physiology of the last thirteen years. But, as he pointed out, the past thirteen years do in a certain sense mark a break between the physiology of the past and that of the future. The last thirteen years have seen the removal of eminent men like Darwin, Claude Bernard, Bowman, Brown-Sequard, Brucke, Du Bois Reymond, Donders, Helmholtz, Ludwig, and Huxley, one prominent inquirer being left in the person of Albert von Kolliker, who "in his old age is doing work of which even he in his youth might have been proud." Despite the great losses in the ranks of physiological students during the last thirteen years physiology has not been idle, and Professor Foster deduced convincing examples in support of this statement. We are nearer a better understanding, he said, as to the exact nature of the fundamental changes which bring about contraction and as to the relations of those changes to the structure of muscular fibre. Then, again, another problem—the beat of the heart—has been strenuously studied with satisfactory results. Again, enormous advances have been made in what Professor Foster said may perhaps be called the new physiological chemistry. He referred mainly to the admirable researches of Kühne on the composition and constitution of proteids, and again to the remarkable work of Emil Fischer on the synthesis of the sugars. He even expressed the hope that as the old problems were attacked by the new chemical method—the old physiological chemistry passing surely but slowly away—we may at any time receive the news "that the stubborn old fortress of the proteids has succumbed to the attack." Finally, Professor Foster dwelt upon the relation of physiology to medicine. Physiology is (Professor Foster says), and always must be, the basis of the science of healing. But, as he pointed out, physiology not only heals, but governs and educates, "and if, as the whole past history of this science leads us to expect in the coming years, a clearer and clearer insight into the nature and conditions of that molecular dance which is to us the material token of nervous action, and a fuller, exacter knowledge of the laws which govern the sweep of nervous impulses along fibre and cell, gives us wider and directer command over the moulding of the growing nervous mechanism and the maintenance and regulation of the grown one, then assuredly physiology will take its place as a judge of appeal in questions, not only of the body, but of the mind; it will raise its voice, not in the hospital and consulting-room only, but also in the senate and the school."

A more interesting historic survey of the progress of botany could hardly have been compiled than is contained in the address to the Botanical Section by its President, Professor H. Marshall Ward. In this address we find the story of bacteriology and its development. Needless to add, the President dwelt considerably upon those researches bearing upon fermentation. Professor Ward some time ago defined alcoholic fermentation as the oldest form of microscopic gardening practised by man, and it is perfectly true. And what an important bearing this has had upon the fermented beverages of the nation. The production of these beverages depends upon the destructive action of certain fungi upon a saccharine liquid, and it is the altered or fermented liquor which is consumed. The theory, however, of alcoholic fermentation seems destined to receive its severest blow by the announcement by E. Buchner of the isolation of an alcoholic enzyme which will convert sugar into alcohol and carbonic acid without apparently the agency of plant life at all. It is impossible to dwell upon the interesting ramifications of Professor Ward's paper, so wide a field does his interesting address cover. Suffice it to mention that in the paper are considered the functions of specific bacteria in the development of quality in butter, cheese, and even tobacco, and the address concluded with an admirable account of those fungi which are antagonistic to our well being. Professor Ward referred to the best means of extinguishing those fungi which are injurious to vines and to hops. As he pointed out, we must learn the habits of the fungus and its life-history before this can be done satisfactorily, or, in other words, see how it is possible to step in at the critical moment and interfere with these relationships in the direction desired by human interests.

If we mistake not the address to the Chemical Section by Professor Ramsay will possess distinct historic importance. He announced the discovery, if we may so put it, of an undiscovered gas. In his laborious work on the properties of argon and helion he was led to surmise the existence of a new gas. In spite of failure to separate this gas, which probably is associated with helion and argon, Professor Ramsay is able to predict the properties of the unknown element. Thus its atomic weight has been approximately fixed, and the new gas, he says, will resemble argon and helion in being indifferent to the action of reagents and in not forming compounds. Listeners to his most interesting address will agree that Professor Ramsay fulfilled his promise to combine a little history, a little actuality, and a little prophecy. The history, as he said, belongs to the old world, and he had endeavoured to share passing events with the new, and hoped that much of the prophecy would meet with its fulfilment "on this side of the ocean."

In his address to the Zoological Section Professor L. C. Miall, expressed his conviction that we study animals too much as dead things. His address dealt mainly with

Digitized by Google

reproduction and animal transformations. The latter subject is, indeed, a most wide one, and, as Professor Miall observed, "how great is the part of adaptation in nature!" But comparatively modern adaptations may be of vital importance to the species and particularly luminous to the student because at times they show us nature at work.

Sir William Turner took as the basis of his address to the Anthropological Section "Some Distinctive Characters of Human Structure," in which he dwelt upon the differences of action between the animal and man, the former being guided by its instincts alone, while the instinctive acts of the latter are under the influence of the reason and intelligence. As the scale of humanity is ascended the more perfect does this control appear, and it was for scientific inquiry to determine, as far as the anatomical conditions will permit, the proportion which the association centres bear to the other centres both in man and other mammals, the period of development of the association fibres in comparison with that of the motor and sensory fibres in different animals, and, if possible, to obtain a comparison in these respects between the brains of savages and those of men of a high order of intelligence.

In the address to the Mathematical and Physical Section Professor A. R. Forsyth took occasion to remark that if in the range of human endeavour after sound knowledge there is one subject that needs to be practical it surely is medicine; yet in the scientific field it has been found that branches such as biology and pathology must be studied for themselves, and be developed by themselves with the single aim of increasing knowledge; and it is then that they can be best applied to the conduct of living processes. So also in the pursuit of mathematics, the path of practical utility is too narrow and irregular, not always leading far, but of the effective assistance which mathematics lends to general natural philosophy there can be no doubt.

These are but a tithe of the papers of equal scientific interest which were read before the Association, but in giving a general and necessarily brief sketch we have confined ourselves to those which have a distinct bearing upon medicine, and are therefore of particular interest to our readers. From the point of view of a record in the annals of science there can be little doubt that the meeting of the British Association in 1897 at Toronto was an unqualified success, and the great objects for which these annual meetings are convened—viz., the gathering together the results of a year's scientific labour, to measure how nearer we are to the truth, to open up or suggest new paths of inquiry, and to encourage and stimulate all those engaged in research for the truth's sake—were more than fulfilled.

UNQUALIFIED PRACTITIONERS AND DEATH CERTIFICATES.

AN adjourned inquest was held on Aug. 5th at the Crown Hotel, Rosedale Abbey, Pickering, Yorkshire, by Mr. W. W. Stenart Corry, deputy coroner, concerning the death of Jane Thompson, aged fifty-six years, who died somewhat suddenly while under the treatment of an unqualified practitioner named Alexander, of Castleton, whose death certificate, to the effect that the deceased died from "inflammation of the bladder and peritonitis," Mr. Thomas Richardson, registrar for the district, refused to accept. The following is an account of the proceedings:—

The evidence of James Thompson, taken at the previous inquiry on July 31st, in which he identified the deceased as his wife, having been read over, Mary Ann Mortimer, daughter-in-law of the deceased, was called. She said that to the best of her knowledge and belief the deceased had not passed any water since the morning of the day previous to her death; during the time she was present nothing was done by way of operation to give relief.

Mr. Geo. Agnew Robertson, of Pickering, who made a post-mortem examination of the body of the deceased, next gave a clear and succinct account of the condition in which he found the various internal organs, all of which he described as healthy except the left lung, which showed signs of an old-standing pleurisy; the heart, which was enlarged, flabby, and empty; and the kidneys, both of which were enlarged, congested, and in a state of acute inflammation. He told the jury he believed that death was due to "failure of the heart, the result of inflammation of the kidneys." He further emphasized the fact that the bladder was empty, contracted, and perfectly healthy.

Thomas Richardson, registrar of births and deaths for the Lastingham sub-district, who while giving his evidence was severely heckled by the foreman of the jury as to his reason for refusing to accept Alexander's death certificate, stated that he did so because the death was sudden, the deceased having been out at work on the day previous to her death, and because the certificate was not signed by a registered medical practitioner.

The evidence of Sergeant Kemp, who was also called, was of an official character, and described his action in carrying out the instructions of the coroner, Dr. Porter, of Hemsley, on whose authority the present inquiry was being held.

The deputy coroner, who had previously sworn himself and given evidence as to the state of health of the deceased when he himself last saw her professionally, about a month before her death, in addressing the jury, pointed out the discrepancy that existed between the result of the post-mortem examination and Alexander's death certificate, the statement in which in no one respect corresponded with the actual facts of the case; he explained the difference between retention of urine and suppression of urine, and pointed out that any operation, even the use of an instrument like a catheter in the latter case, however it might complicate matters, could give no relief, the supposition that the deceased was suffering from retention of urine, the result of inflammation of the bladder, being completely negatived by the medical testimony; he further said that as there was no evidence that Alexander had performed any operation, not even having passed a catheter, and there was no charge of malpractice against him, he, the deputy coroner, did not think it necessary to summon Alexander to appear and give evidence, as he otherwise should have done. Having made these remarks he left it with the jury to say what was the cause of death.

The jury, most of whose sympathies seemed to be on the side of Alexander, the unqualified medical attendant, brought in a verdict of "death from natural causes," adding as a rider that "they were of opinion that the post-mortem examination, the inquest, and the expenses incurred thereby were unnecessary."

BRITISH DENTAL ASSOCIATION.

THE annual general meeting of the British Dental Association, which commenced its proceedings in Trinity College, Dublin, on Aug. 17th, concluded a most successful meeting on Aug. 19th.

Mr. F. Canton, of London, the retiring President, in his valedictory address referred to the progress of dentistry during the last sixty years, and briefly indicated the vast improvements that have been made in the treatment for the preservation of the teeth. Dr. Stack, of Dublin, the incoming President, in an address of great interest to dentists, alluded to the establishment of the new Dental Hospital in Dublin, which owes its origin so much to the stimulus afforded to philanthropic effort by a former meeting of the association in Dublin.

The Rev. Dr. Samuel Haughton, Pro-Provost of Trinity College, on behalf of the University, expressed to the members the gratification the authorities had experienced in welcoming within the College walls such a scientific and educational body as the British Dental Association, and he trusted that on some future occasion when Ireland might be visited a similar opportunity for a display of their goodwill and hospitality might be afforded.

Various reports were read, including those of Mr. W. B. Paterson (London), the honorary secretary; Mr. W. Hern (London), the treasurer; and other business was concluded by the passing of hearty votes of thanks to the local committees in charge of the various sections of the meeting.

Besides many papers and demonstrations of special interest to dental surgeons which were given during the progress of the meeting there were others of considerable value in a general scientific sense; especially was this so in the section devoted to dental microscopy, a subject in which English dentists have already won considerable renown, both at home and abroad.

The social festivities during the meeting included a brilliant reception by the President and Mrs. Stack at the Science and Art Museum on Aug. 18th, attended by over 1500 people, a dinner in hall at Trinity College, and several other entertainments, including two on the invitation of Sir John Banks, K.C.B., and Sir John Power.

The meeting was well attended by members from all parts of England, Scotland, and Ireland, and was generally voted a most successful one.

GUARDIANS AND LUNATICS.

IT is necessary to have some place to which a person suspected of being a lunatic can be taken during the fourteen days set aside by law in which the medical men and justices engaged in the case can come to a conclusion as to whether he is a fit person for removal to an asylum. In the opinion of our legislators the workhouse is deemed the most suitable place, and in most such institutions there is accommodation of a more or less suitable kind for such cases. In the case of wandering lunatics, and whenever a person is in doubt as to whether a friend or relative is bordering on insanity, application is made to the relieving officer of the parish. The relieving officer then lays information before a lunacy justice, and the next move is for the latter to summon to his assistance a qualified medical practitioner. It rests entirely with the justice whom he calls and what fee he orders to be paid to the medical man in such circumstances. It is an order on the guardians to pay a certain sum for the examination of the alleged lunatic. The justice, in most cases, calls in the medical officer attached to the workhouse, because, for obvious reasons, he is more likely to be acquainted with the case, for the alleged lunatic being in the workhouse is under his care day by day, and he can watch the individual more closely than one called in from the outside. Strange to say, nothing is commoner than for the guardians to resist these payments and to try to cut them down. Indeed, it is periodical with some guardians to raise objections to these fees, though on what grounds it is extremely hard to say. The medical officer is an officer of the board, it is true, but the special work which he is called upon by the justice to perform does not come within the scope of his duties as defined by the Local Government Board. It is, moreover, work requiring very special knowledge, both legal and medical. It requires great judgment and necessitates a great deal of time to be spent on any particular case and additional inconvenience in the way of keeping appointments with the justice at unsuitable times, making special written reports, filling in certificates, and, finally, even in the present state of the law, though matters are much improved, considerable risk of an action-at-law is incurred. It seems to us, therefore, that this work should be paid for by extra remuneration, and we fail to understand why the guardians should object to the payment. These gentlemen consist, it is true, as a rule of persons to whom the medical man's salary seems, perhaps, a very large sum; but they forget that the exercise of his profession has necessitated a large expenditure of time and money in the acquisition of special scientific technical knowledge, and in this case the mastering of Acts of Parliament.

We have lately received a copy of a circular letter which runs as follows:—

PARISH OF ST. MARY'S, ISLINGTON.

LUNACY FEES.

Guardians' Offices, St. John's-road, Upper Holloway, N., July 19th, 1897.

DEAR SIR,—I am directed by the guardians of this parish to state that they have had under consideration the subject of the payment of fees in and about the examination of alleged lunatics. In this parish, as in many others, it is the custom for nearly all alleged lunatics dealt with by the parish officers to be admitted into the workhouse under Section 20 of the Lunacy Act, 1890, and they are in due course examined by justices who attend at the workhouse for that purpose. The justice attending always calls to his assistance in his examination the resident medical officer of the workhouse, and in a general way this is, no doubt, the best course. It is part of the duty of such officer to see to the needs of the lunatic before and after examination whilst in the workhouse, and this is covered by the salary he receives; but for the short time the examination takes place a fee is payable. The guardians believe that in many places, especially where there is a large and increasing number of alleged lunatics, dissatisfaction exists in regard to this matter, and that boards of guardians would rather increase the salary of a medical officer to a suitable amount than pay, as now, a salary, with the addition of a capitation fee for every person admitted into the Lunacy Wards.

At the present time there is before the House of Lords a Bill, introduced by the Lord Chancellor, to amend the Lunacy Acts, 1890 and 1891. The guardians of this parish are now asking the Lord Chancellor to introduce a provision into the Bill by which the justice shall call the medical officer of the workhouse or infirmary, as the case may be, to his assistance in the examination, and that it shall be part of the duty of the medical officer as such to render the assistance, reserving, however, the right for the justice to call in another medical man if special circumstances require it.

The guardians are also asking the Local Government Board for their support. If the guardians of your union agree with the proposal it is requested that they will be good enough to cause letters to be sent to the Lord Chancellor and the Local Government Board in support of the same.

I am, dear Sir, yours truly,
EDWIN DAVEY, Clerk.

It is, in other words, one of those periodical attempts on the part of the guardians to deprive one of their most underpaid and overworked officers of legitimate remuneration, and we trust sincerely, for the credit of the various boards of guardians into whose hands this letter may fall, that they will resist this as an injustice to one of their most deserving officials. Guardians are apt to forget how much the chief spending departments of the parish rest in the hands of their medical man, and if they would only take a liberal view of these things and treat their medical officer well they would keep his heart in his work, and would induce him voluntarily to reduce the expenditure of the parish by many hundreds a year. As a matter of fact, the guardians have, as the law now stands, no option in this matter of payment, but we prefer to present the case for their consideration on other and more liberal grounds, and thus to urge them to act fairly towards their medical officers.

OPENING OF THE MEDICAL SCHOOLS.

WINTER SESSION, 1897-98.

METROPOLITAN.

St. Bartholomew's Hospital.—The session will begin on Oct. 1st, and the annual dinner of old students will take place in the Great Hall on the evening of that day.

Charing-cross Hospital.—The session will commence on Oct. 4th, when an introductory address will be delivered in the anatomical theatre of the Medical School at 4 P.M. by Dr. Wm. Carter, Professor of Materia Medica in University College, Liverpool.

St. George's Hospital.—The session will open on Oct. 1st with an introductory address at 4 P.M. by Dr. Patrick Manson. The Medical School dinner will be held in the evening at the Whitehall Rooms, Dr. T. T. Whipham presiding. Dr. Alex Hill, Master of Downing College, Cambridge, will distribute the prizes on Oct. 29th.

Guy's Hospital.—The session will commence on Oct. 4th. On that day the first meeting of the Physical Society will be held and will be preceded by a house dinner at the Students' Club.

King's College Hospital.—There will be a reception and distribution of prizes on Oct. 1st.

London Hospital.—The session will commence on Oct. 1st. The old students' dinner, which will take the place of an opening ceremony, will be held in the library of the Medical College on that evening, the chair to be taken by Dr. A. Ernest Sansom.

Middlesex Hospital.—The session will commence on Oct. 4th, at 3 P.M., when Sir Donald Smith, G.C.M.G., LL.D., Chancellor of M'Gill University, Montreal, will address the students and distribute the prizes. The dinner of the past and present students will take place at the Café Royal on the same evening, Mr. Storer Bennett, F.R.C.S., in the chair.

St. Mary's Hospital.—The session will be opened on Oct. 1st, at 4 P.M., with an introductory address by Dr. William J. Gow. The annual dinner of past and present students will be held the same evening in the King's Hall, Holborn Restaurant. Mr. A. J. Pepper, F.R.C.S., will occupy the chair.

St. Thomas's Hospital.—The session will commence on Oct. 2nd. On the same day, at 3 P.M., the prizes will be distributed in the Governors' Hall, and the annual dinner will take place at the Whitehall Rooms at 6 30 P.M., Sir William MacCormac, Bart., President of the Royal College of Surgeons of England, in the chair.

University College Hospital.—The session will be opened on Oct. 4th, at 4 P.M., when the prizes will be distributed, after which an introductory lecture will be delivered by Mr. Raymond Johnson, F.R.C.S. On the same day, at 6 30 P.M., the annual dinner of the old and present students will be held at the Hôtel Cecil, Victoria-embankment, Dr. H. Charlton Bastian, F.R.S., in the chair.

Digitized by Google

Westminster Hospital.—The session will begin on Oct. 1st. The distribution of prizes, followed by a conversazione, will take place at the Westminster Town-hall on Sept. 30th, at 8.30 P.M.

Royal Free Hospital (London School of Medicine for Women).—The session will begin on Oct. 1st, when the opening address will be given at the Royal Free Hospital, Gray's-inn-road, by Mr. Grosvenor Mackinlay, F.R.C.S. Edin., at 8 30 P.M.

PROVINCIAL.

Mason College, Birmingham.—The opening of the winter session of the Queen's Faculty of Medicine of this College will take place on Oct. 1st. on which, occasion Sir James Crichton Browne, M.D., F.R.S., will deliver the address. In the evening the medical men in Birmingham and the neighbourhood have been invited to meet Sir James Crichton Browne, at a conversazione.

University College, Sheffield, Medical Department.—The Medical School will open on Oct. 1st. The introductory address will be delivered at 4.30 P.M. in the lecture-hall of the College by Dr Philip Henry Pye-Smith, F.R.S., senior physician and lecturer on Medicine, Guy's Hospital.

At *University College, Bristol, Yorkshire College, Leeds, University College, Liverpool*, and *Owens College, Manchester*, the session will commence on Oct. 1st.

SCOTLAND.

Anderson's College Medical School, Glasgow.—The session of this school will open on Oct. 14th. There will be no special function of any kind. Each professor will meet his own students and give them a short introductory address connected more particularly with his own subject.

Western Medical School, Glasgow.—The school will re-open on Oct. 19th.

IRELAND.

Queen's College, Cork.—The session will open on Oct. 19th.

Queen's College, Belfast.—The first term of the session will begin on Oct. 19th.

CHANGES IN THE MEDICAL SCHOOLS AND HOSPITALS.

METROPOLITAN.

St. Bartholomew's Hospital.—During the past year numerous changes have taken place in the medical and teaching staff of the hospital and school. Mr. W. J. Walsham has been appointed Joint Lecturer on Surgery in Mr. H. T. Butlin's place, and Mr. Lockwood has succeeded Mr. Walsham as Lecturer on Anatomy; Dr. F. W. Andrewes is Pathologist and Lecturer on Pathology, vice Dr. Kanthack; Dr. Chattaway takes the place of Dr. W. J. Russell as Lecturer on Chemistry; Dr. P. Horton-Smith has been appointed Assistant Demonstrator of Practical Medicine, and Mr. J. Berry and Mr. D'Arcy Power Demonstrators of Practical Surgery. Mr. D'Arcy Power has also been elected a Demonstrator of Operative Surgery. The Curatorship of the Museum is in the hands of Dr. Andrewes, and Mr. T. S. Pigg acts as Assistant Curator. Dr. F. E. Batten and Dr. J. A. Hayward have been appointed Casualty Physicians. Mr. Bruce Clarke has been appointed Lecturer to Probationary Nurses.

Charing-cross Hospital.—Mr. Wallis has been appointed Lecturer on Operative Surgery in place of Mr. Waterhouse, who was appointed Lecturer on Anatomy. Dr. Arkle has been appointed Vice-Dean in place of Mr. Waterhouse, and Mr. Hardcastle has been appointed Medical Registrar to the hospital to succeed Mr. Senior.

St. George's Hospital.—Dr. Whipham has retired by the twenty-year rule and has became Consulting Physician. Dr. Penrose has been elected as full Physician and Dr. Cyril Ogle as Assistant Physician. Dr. A. Latham has been elected Curator of the Museum, Dr. Davidson and Dr. Fenton have been appointed Medical Registrars, Mr. F. Jaffray Surgical Registrar, and Dr. H. Menzies and Dr. Blumfeld Anæsthetists. Mr. F. S. Collard becomes Demonstrator of Anatomy, Dr. Ewart replaces Dr. Whipham as Joint Lecturer on Medicine, and Mr. Bennett and Mr. Dent lecture on Surgery instead of Mr. Pick.

London Hospital.—Dr. Ramskill, Consulting Physician, who was appointed an Assistant Physician as long ago as 1859, died on June 22nd last. Mr. Walter Rivington, Consulting Surgeon, who was appointed Assistant Surgeon in 1863, died on May 8th last. Dr. Samuel Fenwick has been appointed a Consulting Physician, and Dr. Henry Head has been appointed an Assistant Physician. Mr. Frederick Treves has resigned the Chair of Surgery and has been succeeded by Mr. Mansell Moullin. Physiology and Histology will now be taught by Dr. Leonard Hill and Mr. Hutchinson. Dr. Dawson has been appointed Demonstrator of Materia Medica, Mr. Jenkinson Demonstrator of Biology, and Mr. Roxburgh Teacher of Practical Surgery and Demonstrator of Anatomy. Dr. Bullock has been appointed Bacteriologist to the Hospital and Lecturer on Bacteriology and Pathological Chemist to the College. Dr. Dawson and Dr. Head have been appointed Instructors in Elementary Clinical Medicine, and Medical and Surgical Tutors have been appointed.

Middlesex Hospital.—The hand of death has taken away Dr. Henry Thompson, Consulting Physician, and Mr. Leopold Hudson, Assistant Surgeon and Surgeon in the Ear and Throat Department. Mr. T. H. Kellock has been appointed Assistant Surgeon and Surgical Registrar, and Mr. Stephen Paget Surgeon in the Ear and Throat Department. Dr. C. R. Biss has been appointed Physician to Out-patients. Mr. G. Murray has been appointed Tutor in Surgery, and Mr. Stephen Paget Lecturer in Laryngology and Otology. The Demonstrators for the Session 1897-98 are as follows: Anatomy, Dr. R. Gladstone and Mr. A. S. Fergusson; Physiology, Mr. J. S. Goodall and Mr. N. Navaica; Biology, Mr. J. S. Goodall; and Chemistry, Mr. G. E. Froggatt.

St. Mary's Hospital.—Mr. Owen is now Lecturer on Clinical Surgery, and Mr. Pepper Joint Lecturer on Surgery; Mr. Silcock and Mr. Collier are Joint Lecturers on Operative and Practical Surgery; Dr. Caley is Physician to Out-patients, Lecturer on Materia Medica, and Senior Medical Tutor; Mr. Plimmer, Joint Lecturer on Pathology; Mr. H. S. Collier, Surgeon to Out-patients and Warden of the College; Dr. J. F. H. Broadbent, Casualty Physician; Dr. F. J. Poynton, Medical Registrar; Mr. V. W. Low, Surgical Registrar; Dr. W. J. Harris, Junior Medical Tutor and Editor of the *Gazette*; Dr. A. F. Bill, Curator of the Museum and Demonstrator of Pathology; and Dr. E. J. Steegman, Demonstrator of Hygiene.

Westminster Hospital.—The changes on the hospital staff are the appointment of Mr. Macnamara as Consulting Surgeon, Mr. W. G. Spencer as Surgeon, and Mr. W. Turner as Assistant Surgeon. Dr. Dupré has relinquished the post of Lecturer on Chemistry after having held the chair for thirty-three years and has been succeeded by Dr. Wilson Hake. Dr. Hebb has become Dean on the retirement of Mr. Spencer, and Mr. A. H. Tubby has been appointed Vice-Dean.

St. Thomas's Hospital.—Sir Felix Semon has resigned his charge of the Throat Department, and his successor will shortly be appointed. Dr. Barry Blacker has been appointed Superintendent of the x-ray Department, and Dr. L. L. Jenner Superintendent of the new Clinical Laboratory. Dr. C. R. Box has been appointed Resident Assistant Physician, and Mr. C. S. Wallace Resident Surgeon; while Dr. A. E. Russell, Mr. E. O. Thurston, and Dr. A. F. Stubb have been appointed Medical, Surgical, and Obstetric Registrars respectively.

PROVINCIAL.

Sheffield School of Medicine.—Dr. C. Addison has been appointed Arthur Jackson Professor of Anatomy in the New College, Dr. Hugh Rhodes Lecturer on Forensic Medicine in place of Dr. Harvey Littlejohn, Dr. Andrew Walker Demonstrator of Bacteriology, Mr. Baynes Smith Laboratory Assistant in the Physiological Department, Dr. John Robertson Lecturer on Public Health, and Mr. A. Cuff and Mr. L. T. Giles have been appointed Demonstrators of Anatomy.

Mason College, Birmingham.—Dr. Robert M. Simon, Physician to the General Hospital, has been appointed Professor of Forensic Medicine, in place of Professor J. St. S. Wilders, who has been compelled, owing to ill-health, to resign the chair which he has occupied for thirty years. The council have appointed him an Emeritus Professor. Dr. Swale Vincent, having been

Digitized by Google

appointed Research Scholar of the British Medical Association, has vacated the position of Demonstrator of Physiology, and has been succeeded by Dr. J. S. Bolton. The Lectureships in Ophthalmology and Operative Surgery have been constituted Professorships, and Professor Priestley Smith and Professor Jordan Lloyd have been elected to fill these chairs. Mr. C. Leedham-Green, surgeon to out-patients at the Queen's Hospital, has been appointed Assistant Lecturer in Bacteriology.

University College, Bristol.—Mr. C. A. Morton, F R C S., and Dr. J. Swain, M.S. Lond., have been appointed Joint Professors of Surgery, in the place of the late Mr. Greig Smith.

SOME LITERATURE CONCERNING THE PLAGUE.

WE have already alluded very briefly to some recently published reports[1] regarding the plague, and we may now notice them somewhat more in detail, although it will be difficult, if not impossible, to do so at any length, seeing that the literature on the subject is somewhat voluminous. Taking them in chronological order we may start with the report regarding the prevalence of bubonic plague in the colony of Hong-Kong during the years 1895 and 1896 by the Acting Colonial Surgeon, J. M. Atkinson, M.B. Lond., D.P.H. Camb. This, it will be seen, deals only with the history of the disease in Hong-Kong during those years and refers to the able report by Dr. Lowson, Acting Superintendent, Government Civil Hospital, for the history of the epidemic in 1894. In view of the important practical questions that have engaged, or are engaging, the attention of many experts in Europe and India, the author has endeavoured to set forth such deductions as seemed to him reasonably warranted from the data at his command and to enumerate the more important facts to be noted in preventing or limiting the occurrence and spread of the disease.

The report contains a brief history of the plague in China and Hong-Kong during modern times, drawn from that by Dr. Rennie on the disease at Canton in 1894 contained in the Imperial Maritime Customs Medical Reports, and from Allbutt's System of Medicine, 1896, together with a sketch plan drawn to scale showing the several places referred to and illustrating the progress and route taken by the disease. Touching the prevalence of plague in Hong-Kong in 1895 it is shown that the total number of cases reported was forty-four; that the disease commenced at the end of April and continued more or less during the remainder of the year; that the greatest number of cases occurred during the months of June and December, but that the disease did not assume such proportions as to constitute an epidemic; and that, with the exception of Heung-lane, in no portion of the colony did it obtain any serious hold. The procedure adopted on the receipt of information that the disease had re-appeared consisted of house-to-house visitation, the removal and segregation of the sick, together with the isolation of the infected, the notification of infected localities, and the application, general and special, of sanitary regulations, disinfection, cleansing, the removal of overcrowding, and the strict and steady application of the powers conferred by public health ordinances to tenements, lodging-houses, &c. The condition of Hong-Kong as regards the overcrowding of houses on a given space, their vicious construction of cock-lofts, mezzanine floors and back-yard obstructions, involving overcrowding, absence of light, ventilation, cleanliness and decency, was something terrible and called for wholesale changes in every direction. Although much has probably been done of late years under the pressure and influence of the alarm caused by the epidemic of plague it is impossible to believe that there does not even now remain a good deal to be carried out in the same direction. Passing from the sanitary and prophylactic measures required in this and in all cases of epidemic disease, we come to the medical aspect of plague. The pathology, symptoms, and morbid anatomy having been described in Dr. Lowson's report of the plague in 1894 and in Dr. Wilm's later report, the author confines himself to the facts elicited by the further experience of 1896, and the following are some of the facts and deductions set forth in his report. The main channel by which the bacillus gains access to the body appears to be the digestive tract; infection by the skin (inoculation) is relatively rare, and the immunity of those who attended plague patients or were engaged in the inspection and disinfection of infected houses shows that the plague bacillus is not commonly received by the respiratory tract through the medium of the air. The plague bacillus was not detected, it may be mentioned, in the course of many examinations of hospital ward air made for that purpose. Rats, mice, monkeys, pigs, and fowls have been proved to have acquired plague after having been fed with fragments of organs of animals that have died from the disease. In addition to the fæces, the bacillus leaves the body by the urine, as demonstrated by the result of culture experiments. The period of incubation seems to be generally from three to five days, although one case is related by Dr. Wilm of fifteen days. About 70 per cent. of the deaths of those attacked by the disease took place during the first six days. In 95 per cent. of the cases albumin was found in the urine, varying in amount from one-tenth to one-half.

The general conclusions to be drawn from the experience of bubonic plague in Hong-Kong in 1895 and 1896 are stated in the report as follows:—*A.* That the occurrence of plague is favoured by: (1) Long prevalence of drought or of abnormally low rainfall; (2) atmospheric temperature below 82° F.; (3) absence of sunshine; and (4) general insanitary conditions such as obstruction to the free access of light and air to domestic dwellings. *B.* That the steps to be taken to retard the progress of the disease are: (1) General cleanliness and the free admission of light and air to domestic dwellings; (2) the immediate isolation of the sick and those who have been in close contact with the disease; and (3) the careful and systematic disinfection of all premises in which cases occur and of latrines.

(To be concluded.)

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Enteric Fever at Hucknall Torkard, by Dr. Buchanan.[1]—Hucknall Torkard, a small town in Nottinghamshire of some 15,000 inhabitants, has more than once suffered from enteric fever, and last year no less than 141 cases were reported there. In considering the causes of this outbreak Dr. Buchanan arrived at the conclusion that there had been no common infection by reason of occupation, food, or milk; that in view of the two distinct systems of sewers these could not be held to be primarily responsible; and that there was no evidence that the public water-supply, which was general to the whole town, had caused the epidemic or was exposed to any source of pollution. But there had been a heavy incidence of the disease on certain streets and localities, and in a number of houses the occurrence of multiple attacks was remarkable. Detailed investigation of such localities brought out the fact that there were present frequent conditions of dirt, unpaved and badly-drained yards, pollution of soil from waste water and soakage of middens, undue overcrowding, and conditions affecting pail-closets which favour retention of infection. These are conditions which notoriously facilitate the spread of enteric fever, they are conditions which are known by those who have only the most superficial knowledge of public health to be those which sanitary administration should deal with; and yet in certain towns like this one they are allowed to persist to the danger of public health year after year. Nothing accounts for persistently recurring enteric fever more than does the disgraceful practice still so common in many parts of England of storing up excreta and refuse in close proximity to dwellings in receptacles open to rainfall

Digitized by Google

and sun and sunk into the ground. If people had wanted to design something which by fouling the air; by polluting food supplies in pantries, &c., opening on to back yards; and by storing up infection in a polluted soil would ensure recurring typhoid fever, midden-systems such as those which exist in Hucknall Torkard and other places would certainly have to be accredited with having achieved the end aimed at. It is to be hoped that after this renewed experience the District Council will amend these dangerous conditions by carrying out the recommendations attached to Dr. Buchanan's report.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Blackpool Urban District.—Dr. Jasper Anderson traced, he thinks, during the year 1896 an epidemic of enteric fever to the consumption of mussels which were procured from a spot where the sea water had an opportunity of becoming fouled by sewage. It seems that there were 21 cases notified in October, as against 8 in September and 8 in November; and in 10 out of the 21 cases notified in October a history of eating mussels was obtained. It seems, however, that in certain cases the period which elapsed between the consumption of the mussels and the development of the disease was rather long for enteric fever. A complication is introduced, too, by the seasonal increase of enteric fever occurring at a time when the mussels are regarded as in good condition at Blackpool. However, we have little doubt that enteric fever may be conveyed by sewage-polluted mussels, and we quite agree with Dr. Anderson as to the desirability of preventing their consumption.

Southampton Urban District.—The recent extension of this borough has done much towards bringing its population up to 100,000, and it was estimated for 1896 at 98 002. Mr. Wellesley Harris, owing to the necessary uncertainty of the estimate under conditions of extensive and of considerable immigration, urged the desirability of a census being taken, but the council was unwilling, it appears, to undertake the task. The general death-rate of the district was for 1896 16·47 per 1000, as against a rate of 18 27 in 1895, the rate for the town proper being 17·63. There were nine cases of small-pox notified during the year, several of them being imported by ships frequenting the port. One case was apparently caused by a bag of dirty linen sent home from the Cape. The history of 1896 *re* small-pox teaches, Mr. Harris observes, the wisdom of having provided the floating hospital in which the cases were well isolated. In former years the introduction of a case of small-pox into the old hospital appears to have been liable to cause the spread of the disease to the surrounding district. Scarlet fever became epidemic in Southampton during the year, and the hospital accommodation was quite inadequate to deal with it, only 31 per cent. of the cases being isolated. Mr. Harris thinks that had there been sufficient accommodation the epidemic would have been much curtailed, and he furnishes instances in support of his contention. Everything seems to have been done to control the epidemic, and the public were educated up to their responsibilities by means of leaflets, &c. Under these circumstances we are glad to learn that the sanitary authority have acquired a suitable hospital site, and have applied to the Local Government Board for sanction to borrow £30,000 for the erection of a hospital. School closure was resorted to on two occasions for preventing the spread of measles, and in each case this action, Mr. Harris states, was attended with excellent results. Complaints in reference to the discharge of sewage on the foreshore have been made from time to time, and it has, it seems, been decided by the Council to accept the proposal of Mr. Harris to collect and treat the sewage and to discharge the purified effluent at one point on the ebbing tide. Mr. Harris advocates that samples of the effluent should be taken regularly and submitted to the borough analyst for examination.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 7195 births and 6212 deaths were registered during the week ending Saturday, August 14th. The annual rate of mortality in these towns, which had increased in the six preceding weeks from 14·7 to 26·9 per 1000, further rose during the week to 29·5. In London the rate was 26·2 per 1000, while it averaged 31·7 in the thirty-two provincial towns. The lowest death-rates in these towns were 14·6 in Swansea, 15·8 in Halifax, 16·4 in Croydon and in Huddersfield, and 18·2 in Bristol; the highest rates were 39·6 in Salford, 40·9 in Liverpool, 42·6 in Preston, and 43·0 in Birmingham. The 6212 deaths in these towns included 2368 which were referred to the principal zymotic diseases, against 1337 and 1994 in the two preceding weeks; of these, 2038 resulted from diarrhœa, 134 from measles, 70 from whooping-cough, 54 from diphtheria, 36 from scarlet fever, and 36 from "fever," principally enteric. The lowest death-rates from these diseases were recorded in Halifax, Bristol, Swansea, and Huddersfield; and the highest rates in Salford, Leeds, Sheffield, Preston, and Birmingham. The greatest mortality from measles occurred in Swansea, Birmingham, Birkenhead, Salford, Blackburn, and Preston; from scarlet fever in Huddersfield; from whooping-cough in Plymouth, Wolverhampton, and Blackburn; from "fever" in Derby; and from diarrhœa in Birmingham, Leicester, Nottingham, Liverpool, Leeds, and Sheffield. The 54 deaths from diphtheria included 38 in London, 3 in Birmingham, and 3 in Leicester. No fatal case of small-pox was registered during the week in any of the thirty-three large towns; and there were no small-pox patients under treatment in any of the Metropolitan Asylum Hospitals on the 14th inst. The number of cases of scarlet fever in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3341, against numbers increasing from 2380 to 3239 on the fourteen preceding Saturdays; 347 new cases were admitted during the week, against 396, 390, and 376 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 146 and 156 in the two preceding weeks, declined during the week to 118, and were 63 below the corrected average. The causes of 68, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Manchester, Hull, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Leicester, Liverpool, Sheffield and Sunderland.

In thirty-three of the largest English towns 6796 births and 6058 deaths were registered during the week ending Aug. 21st. The annual rate of mortality in these towns, which had increased in the seven preceding weeks from 14·7 to 29·5 per 1000, declined again last week to 28·7. In London the rate was 24·2 per 1000, while it averaged 31·8 in the thirty-two provincial towns. The lowest death-rates in these towns were 12·0 in Halifax, 12·8 in Huddersfield, 17·2 in Swansea, and 18·9 in Bristol; the highest rates were 42·9 in Birmingham, 45·2 in Hull, 45·3 in Preston, and 52·6 in Wolverhampton. The 6058 deaths in these towns included 2319 which were referred to the principal zymotic diseases, against 1994 and 2368 in the two preceding weeks; of these, 1997 resulted from diarrhœa, 138 from measles, 74 from whooping-cough, 42 from diphtheria, 34 from scarlet fever, 34 from "fever" (principally enteric), and not one from small-pox. The lowest death-rates from these diseases were recorded in Huddersfield, Halifax, Swansea, and Oldham; and the highest rates in Manchester, Birmingham, Wolverhampton, Hull, and Preston. The greatest mortality from measles occurred in Salford, Blackburn, Birmingham, Manchester, and Preston; from scarlet fever in Wolverhampton; from whooping-cough in Gateshead; and from diarrhœa in Leeds, Manchester, Burnley, Salford, Leicester, Birmingham, Wolverhampton, and Hull. The mortality from "fever" showed no marked excess in any of the large towns. The 42 deaths from diphtheria included 29 in London and 3 in Liverpool. No fatal case of small-pox was registered last week in any of the thirty-three large towns, and no small-pox patients were under treatment in any of the Metropolitan Asylum Hospitals during the week ending Saturday last, the 21st inst. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3400, against 3106, 3239, and 3341 on the three preceding Saturdays; 340 new cases were admitted during the week, against 360, 376, and 347 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 156 and 118 in the two preceding weeks, were 119 last week, and were 53 below the corrected average. The causes of 61, or 1·0 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a

Digitized by Google

coroner. All the causes of death were duly certified in Cardiff, Salford, Oldham, Sunderland, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Liverpool, Burnley, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·2 and 20·5 per 1000 in the two preceding weeks, declined again to 19·0 during the week ending August 14th, and was 10·5 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·2 in Aberdeen and 14·4 in Edinburgh to 23·7 in Greenock and 25·6 in Perth. The 565 deaths in these towns included 113 which were referred to diarrhœa, 18 to whooping-cough, 12 to scarlet fever, 7 to measles, 4 to "fever," and 2 to diphtheria; in all, 156 deaths resulted from these principal zymotic diseases, against 89 and 137 in the two preceding weeks. These 156 deaths were equal to an annual rate of 5·2 per 1000, which was 6·0 below the mean rate for the week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 35, 51, and 87 in the three preceding weeks, further rose to 113 during the week, of which 79 occurred in Glasgow, 12 in Greenock, and 6 in Dundee. The 18 deaths referred to whooping-cough showed a decline of 4 from the number recorded in the preceding week, and included 9 in Glasgow and 6 in Edinburgh. The fatal cases of scarlet fever, which had been 5 and 8 in the two preceding weeks, further rose to 12 during the week; 9 occurred in Edinburgh and 2 in Dundee. The 7 deaths from measles showed a marked decline from the number in the preceding week and included 4 in Leith. Of the 4 deaths referred to different forms of "fever" 2 were recorded in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 66 and 71 in the two preceding weeks, declined to 58 during the week, and were 13 below the number in the corresponding week of last year. The causes of 38, or nearly 7 per cent., of the deaths in these eight towns during the week were not certified.

The annual rate of mortality in the eight Scotch towns, which had been 20·5 and 19·0 per 1000 in the two preceding weeks, rose again to 21·6 during the week ending Aug. 21st, but was 7·1 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·6 in Perth and 16·9 in Aberdeen to 24·2 in Dundee and 31·3 in Greenock. The 643 deaths in these towns included 147 from diarrhœa, 21 from whooping-cough, 6 from measles, 5 from scarlet fever, 4 from diphtheria, and 4 from "fever." In all, 187 deaths resulted from these principal zymotic diseases, against 137 and 156 in the two preceding weeks. These 187 deaths were equal to an annual rate of 6·3 per 1000, which was 4·7 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 51, 87, and 113 in the three preceding weeks, further rose to 147 last week, of which 89 occurred in Glasgow, 21 in Greenock, 8 in Edinburgh, and 8 in Dundee. The 21 deaths referred to whooping-cough exceeded by 3 the number in the preceding week, and included 16 in Glasgow, 2 in Edinburgh, and 2 in Dundee. The 6 fatal cases of measles showed a slight further decline from those registered in recent weeks, and included 3 in Leith. The deaths from scarlet fever, which had increased from 5 to 12 in the three preceding weeks, declined again to 5 last week, of which 4 occurred in Glasgow. The 4 fatal cases of "fever" corresponded with the number recorded in the preceding week, and included 3 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 71 and 58 in the two preceding weeks, were 62 last week, and slightly exceeded the number in the corresponding period of last year. The causes of 36, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the four preceding weeks from 24·2 to 22·4 per 1000, rose again to 26·5 during the week ending August 14th. During the first six weeks of the current quarter the rate of mortality in the city has averaged 23·5 per 1000, the rate during the same period being 21·2 in London and 18·8 in Edinburgh. The 178 deaths in Dublin during the week showed an increase of 28 upon the number in the preceding week, and included 51 which were referred to the principal zymotic diseases, against 14 and 25 in the two preceding weeks; of these 39 resulted from diarrhœa, 5 from whooping-cough, 4 from "fever," and 3 from scarlet fever. These 51 deaths were equal to an annual rate of 7·6 per 1000, the zymotic death-rate during the same period being 8·5 in London and 4·1 in Edinburgh. The fatal cases of diarrhœa, which had increased from 2 to 18 in the four preceding weeks, rose to 39 during the week. The mortality from whooping-cough and from "fever" considerably exceeded that recorded in any recent week. The deaths referred to scarlet fever, which had been 1 and 4 in the two preceding weeks, declined to 3 during the week. The 178 deaths registered in Dublin included 42 of infants under one year of age and 32 of persons aged upwards of sixty years; the deaths of infants showed a slight increase, while those of elderly persons were slightly below those recorded in the preceding week. Twelve inquest cases and 6 deaths from violence were registered; and 49, or more than a fourth, of the deaths occurred in public institutions. The causes of 12, or nearly 7 per cent., of the deaths in the city during the week were not certified.

The death-rate in Dublin, which had been 22·4 and 26·5 per 1000 in the two preceding weeks, declined again to 24·3 during the week ending Aug. 21st. During the past seven weeks of the current quarter the rate of mortality in the city has averaged 23·6 per 1000, the rate during the same period being 21·6 in London and 18·5 in Edinburgh. The 163 deaths registered in Dublin during the week under notice showed a decline of 15 from the number in the preceding week, and included 39 which were referred to the principal zymotic diseases, against 25 and 51 in the two preceding weeks; of these, 31 resulted from diarrhœa, 3 from scarlet fever, 2 from whooping-cough, 2 from "fever," and 1 from measles. These 39 deaths were equal to an annual rate of 5·8 per 1000, the zymotic death-rate during the same period being 7·7 in London and 2·7 in Edinburgh. The fatal cases of diarrhœa, which had increased from 2 to 39 in the five preceding weeks, declined to 31 last week. The deaths referred to scarlet fever, which had been 4 and 3 in the two preceding weeks, were again 3 last week. The mortality from whooping-cough and from "fever" showed a decline from that recorded in the preceding week. The 163 deaths in Dublin last week included 48 of infants under one year of age, and 28 of persons aged upwards of sixty years; the deaths of infants showed a further increase, while those of elderly persons showed a slight further decline from those recorded in recent weeks. Seven inquest cases and 4 deaths from violence were registered; and 55, or rather more than a third, of the deaths occurred in public institutions. The causes of 10, or more than 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT-COLONEL CALEB K. POWELL retires on retired pay. The under-mentioned Surgeon-Majors to be Surgeon-Lieutenant-Colonels: William T. Johnston, Abraham W. Browne, Robert D. Hodson, Hugh C. Kirkpatrick, John Armstrong, William W. Kenny, Philip M. Ellis, and James F. Brodie. The under-mentioned Surgeons on probation to be Surgeon-Lieutenants: Stevenson Lyle Cummins, Joseph McArdle, Charles Hensley Hopkins, Lewis Julius Christopher Hearn, Peter McKessack, John McDonald McCarthy, Ernest Brodribb, John Poe, Henry Lawrence Weekes Norrington, Hamilton George Frampton Stallard, Robert Dalkeith Jephson, and Arthur Winniett Nunn Bowen.

Surgeon-Captain C. J. W. Tatham will embark for service at Mauritius next month. Brigade-Surgeon-Lieutenant-Colonel F. Lyons has joined at Colchester for duty.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Captain J. Gould (Bengal) are replaced at the disposal of the Military Department, and also those of Surgeon-Captain Cleveland (Bombay), Surgeon-Captain Seton (Bengal), Surgeon-Lieutenant James

Digitized by Google

(Madras), and Surgeon-Lieutenant Dee (Madras). Surgeon-Lieutenant-Colonel Cook is appointed to be Surgeon, 3rd District, Madras, in succession to Brigade-Surgeon-Lieutenant-Colonel H. J. Hazlett, retired. Surgeon-Lieutenant-Colonel G. L. Walker to be Surgeon, 1st District, Madras, and Medical Inspector of Emigrants, vice Surgeon-Lieutenant-Colonel Cook. Surgeon-Lieutenant-Colonel W. A. Lee is appointed to be District Medical and Sanitary Officer, Tanjore, vice Surgeon-Lieutenant-Colonel G. L. Walker. Surgeon-Major J. C. Marsden is appointed to be District Medical and Sanitary Officer, South Arcot, vice Surgeon-Lieutenant-Colonel W. A. Lee. Surgeon-Major A. J. O'Hara is appointed to be District Medical and Sanitary Officer, Godavery, vice Surgeon-Major J. C. Marsden. Surgeon-Major W. F. Thomas, M.D., is appointed to be District Medical and Sanitary Officer, Cuddapah, vice Surgeon-Major A. J. O'Hara. The services of the undermentioned officers are replaced at the disposal of the Government of India, Home Department:—Surgeon-Captain W. P. Barter, A.M.S., Surgeon-Lieutenant E. R. Steel, A.M.S. The services of Surgeon-Lieutenant F. Wall (Madras) are placed temporarily at the disposal of the Chief Commissioner of the Central Provinces for employment on famine duty. Transfers:—Surgeon-Captain C. Thomson, Supernumerary Civil Surgeon, from Aligarh to Fatehgarh. Surgeon-Lieutenant C. B. Harrison, on plague duty, from Agra to Jhansi. Surgeon-Lieutenant C. H. Bensley, on plague duty, from Cawnpore to Meerut. Surgeon-Captain A. W. Dawson from plague duty at Hardwar to that at Saharanpur.

NAVAL MEDICAL SERVICE.

The following appointments are announced: — Staff Surgeons: William E. Horne, M.D., B.Sc., to the *Tamar;* Richard A. Fitch to the *Barrosa;* Henry B. Beatty to the *Royalist;* William Spry to the *Calypso;* Robert Hickson to the *Philomel;* John Lowney to the *Melampus;* and Cyril J. Mansfield, M.D., to the *Hotspur.* Surgeons: Charles S. Facey, M.B., to the *Pembroke,* and Louis E. Dartnell to the *Triton.*

Staff Surgeon Henry William Duffield Walsh has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

ARMY MEDICAL RESERVE OF OFFICERS.

The under-mentioned officers having resigned their Volunteer appointment, cease to belong to the Army Medical Reserve of Officers:—Surgeon-Lieutenant-Colonel Thomas Michael Dolan and Surgeon-Captain John Cunningham.

VOLUNTEER CORPS.

Artillery: 2nd Cheshire (Railway): James Reginald Atkinson, gent., to be Surgeon-Lieutenant. *Rifle:* Galloway: Surgeon-Captain R. Bell Lorraine resigns his commission. 1st Volunteer Battalion the Hampshire Regiment: Surgeon-Lieutenant W. A. Griffiths to be Surgeon-Captain. 19th Middlesex (St. Giles's and St. George's, Bloomsbury): Surgeon-Captain Alexander MacGregor, M.D., from the Volunteer Medical Corps (Aberdeen Company), to be Surgeon-Captain.

VOLUNTEER MEDICAL STAFF CORPS.

The Aberdeen Company: The resignation of Surgeon-Captain A. MacGregor, is cancelled.

THE INDIAN NEWS AND THE MEDICAL SERVICES.

It has often been said that the British are a warlike but not a military people, and we certainly generally manage to be engaged in some small war or other. At the present time we have many expeditions and wars on our hands. On the Indian frontier there is the expedition in the Chitral-Swat district, that in the Trochi valley, and the tribal outbreak on the Khyber-Peshawar border, to say nothing of the Nile expedition in the Soudan, the fighting in South Africa and in other parts of the world. The fact is that our empire is so extensive and widely spread that it is nearly hopeless to expect there will be peace throughout the whole extent of our territories at any given time; it is one of the responsibilities of our position that we must always be ready to meet and repel an attack somewhere or other. By far the most important news at the present time comes from India regarding the serious outbreak of the tribes, and especially of the large and powerful tribe of Afridis, in the Khyber Pass, and of their attack in force on the posts in the immediate vicinity of Peshawar. That the Government of India regard the situation as serious and the disaffection as likely to spread to other places and tribes on the frontier, and give rise to much future trouble and expense, is clear from the large force that has been concentrated on the frontier generally and in the vicinity of the Khyber Pass, at Khohat, and other places. Those medical officers who took part in the last Afghan wars will be familiar with the country and with the names of the posts and districts occupying a more or less prominent place in the descriptions that are appearing in the papers regarding these tribal revolts. It is nearly certain that the Ameer of Afghanistan has taken no active part whatever in these outbreaks; the most that can be said is that he does not seem to have shown any alacrity in warning the Indian Government or in attempting to repress them. These wars on the frontier are not to be reckoned as a source of any serious danger to our power in India, so long as they are not so successful as to damage our prestige, but they are very costly and embarrassing. We have now a large and splendid European army in India, and the native army is in a high state of efficiency, reliable and well-affected to the Indian Government, its main source of weakness being that it is greatly under-officered as far as British officers are concerned. All the medical officers on leave in this country from India have been recalled. The work imposed upon the medical officers of both the British and Indian services is unusually arduous, and it behoves the War Office authorities in this country to lose no time in doing all they can to render the Army Medical Service more attractive to candidates, for medical officers must be greatly required under existing conditions in India.

THE POONA ALLEGATIONS.

It is an old story now, but we do not think that the retractation of Professor Gokhale could be put more strongly or succinctly than it was in his telegram to H.E. the Governor of Bombay, preliminary to the reception of his more extended report: "Have just posted full statement containing explanation, full retractation, and unqualified apology." Lord Sandhurst, the Governor of Bombay, in closing the late Budget discussion, according to the *Times of India* of the 6th inst., made a strong statement vindicating his policy with regard to the plague. The continued prevalence of plague and famine had strained, not only the powers, but the utmost possibilities of the administration of the Government. His lordship characterised the statements that had been made against the action of the authorities as ridiculous, ruthless, and heartless allegations. The operations for the suppression of the plague in Poona were carried out with the utmost regard to decency and the feelings of the people.

DEATHS IN THE SERVICES.

Surgeon-General William Henry Muschamp (retired), aged sixty-four years, on the 21st inst. He entered the service in 1855 and served in the Crimea, being present at the siege and fall of Sevastopol and the attack of Sept. 8th, 1855 (medal with clasp and Turkish medal). He served also in the North-West Provinces in suppressing the Mutiny of 1857–58, and was present at the operations at Cawnpore, the actions of Kali Nadi and Khankur, the capture of Bareilly, the relief of Shahjehanpur and the affairs of Mahomdi, Shahabad, and Bunkagahon (medal).

ENTERIC FEVER AT CHERAT.

The *Times of India* reports that there has been a severe outbreak of enteric fever at Cherat. One officer, fifty men, two women, and a child are in hospital from that disease.

SURGEON-CAPTAIN P. HEHIR.

The Bombay Government have refused the extension of this officer's services for five years in the Nizam's State, and he consequently reverts to the Bengal Medical Service.

THE MERTHYR TYDVIL GENERAL HOSPITAL.—The half-yearly meeting of this hospital was held on Aug. 12th. The report showed that during the half year ended June 30th 100 in-patients had been admitted. The balance standing to the credit of the institution on Jan. 1st was £429, and £571 had been received since then, making a total of £1000. The expenditure for the six months amounted to £800. It was stated that of the £10,000 proposed to be raised for the endowment of the Diamond Jubilee Ward only £1000 was still required to make up that amount.

Correspondence.

"Audi alteram partem."

"HOSPITAL ABUSE."

To the Editors of THE LANCET.

SIRS,—Will you kindly announce that we are organising a conference on the hospital reform question and that we propose to deal more especially with the administration of the out-patient department and with the formation of a Central Hospital Board? The dates provisionally fixed are Oct. 20th and 21st. Sir Henry Burdett and Mr. C. S. Loch have already expressed their willingness to take part, and I should be glad to hear from others who would like to do so also.

I am, Sirs, yours faithfully,

T. GARRETT HORDER,
Honorary Secretary, Hospital Reform Association.

Cardiff, Aug. 17th, 1897.

To the Editors of THE LANCET.

SIRS,—I also fail to understand the charges of unfairness directed at your Special Commissioner, whose accurate gauge of the present situation and also the able manner in which he has presented every side of the question is to be commended. Undoubtedly the enemies of the medical profession are to be found in its own ranks, as instance the deplorable fiasco, the moribund Leicester Medical Union. The committee rejected the resolutions of the sub-committee; they then formed deputations to wait upon every dispensary and club management, and even then some benefit would have accrued if some five or six medical officers to the provident dispensary, whilst yet being members of the said union, had not met privately at one of their own houses and drew up a resolution requesting the manager of the provident dispensary to notify some twenty odd of their fellow medical officers to this effect—viz., that if they were not satisfied to tender their resignation. So that these few dealt the death-blow to the said union and reinstated their manager again, directly and indirectly, master of the local medical profession.

I am, Sirs, yours faithfully,

ERNEST WILLIAM HAYDON, M.B. Glasg.

Leicester, Aug. 23rd, 1897.

"AMYLACEOUS DYSPEPSIA."

To the Editors of THE LANCET.

SIRS,—Since the introduction of taka diastase some attention has been given to amylaceous dyspepsia; but the indiscriminate praise which is being given to that drug, of which Dr. Taylor's paper in THE LANCET of Aug. 7th is an example, can only lead to its indiscriminate use and subsequent neglect. The great fault of the papers on this form of dyspepsia is that they say nothing about its cause, not a single word as to why the fermentation began originally. And the treatment of the disease is as defective; the main advice is to use taka diastase, and in a secondary, half-hearted way we are advised to look after the eating and the drinking. Fenwick strongly advises a man whenever possible to get at the cause, as in treatment a knowledge of the cause is at least as important as the diagnosis, and this is especially true of the diseased conditions known as dyspepsia. Does the defect lie in the quantity and quality of the food, or in the saliva, the teeth, or the stomach? If the saliva be deficient, as, for example, in fevers, give taka diastase; but as it has never been shown to be deficient in dyspepsia there must be some cause for its defective action during the period that intervenes before the HCl is in sufficient amount to stop its action. The causes of amylaceous dyspepsia are bolting the food, badly chewed food where the teeth are rotten and deficient, badly cooked pastries (in these three conditions the saliva never gets intimately mixed with the food), and pastry made from rancid butter or lard when the butyric acid is carried ready made into the stomach. It is easy to see that taka diastase alone must be of very temporary benefit, and that the treatment must begin with removal of the cause, and the defect pointed out to the patient. Not long ago I saw two patients in consultation who had had all kinds of drugs administered to them for their dyspepsia (one gentleman had got tired and had given up drugs), but whose teeth had never been looked at. In these two, as in many others in the past, cure was attained by attention to eating, no drug except a bismuth lozenge being used (Sir W. Roberts's method, but not his lozenge, which I have found inferior to the ordinary bismuth lozenge). New teeth must be ordered when necessary, bolters must chew their food dry, flesh meat must in many cases be minced, the quantity of starchy matter and sugar decreased in others, and in all no tea must be drunk, not even tasted, till the end of the meal. Taka diastase will aid and will often be of more use than a dinner pill. To turn for a moment to a physiological question. Dr. Boyd speaks of the products of the digestion of starch by taka diastase being absorbed by the stomach. Does this take place? Does it not rather take place, if not altogether, at least to a very large extent in the intestines?

I am, Sirs, yours faithfully,

JAMES GARDNER.

Chorlton-on-Medlock, Manchester, Aug. 25th, 1897.

"A NOTE ON ARTIFICIAL PUPIL."

To the Editors of THE LANCET.

SIRS,—Dr. Bell Taylor is usually so well informed in all ophthalmic subjects that I confess to a feeling of surprise when I find him indulging in ancient history in his note on artificial pupil in THE LANCET of Aug. 14th. The operation which he there describes was performed by my late father as far back as 1867, and he subsequently used it on many occasions within my knowledge. I have operated by this method both in my hospital and private practice for more than twenty years, and I have every reason to believe that it has long been in general use amongst ophthalmic surgeons.

I am, Sirs, yours faithfully,

G. ANDERSON CRITCHETT.

Harley-street, W., Aug. 14th, 1897.

WHAT IS THE CAUSE OF DIPHTHERIA?

To the Editors of THE LANCET.

SIRS,—Where does diphtheria originate? and why is it that with all the advance in sanitary reform that has been made in the last twenty-five years the disease is on the increase? These two questions need answering if further progress is to be made with this particular disease. I believe the answer to the second question to be that microscopic investigation has been directed to material derived from the patients instead of material taken from their surroundings.

We all know that in some way or other dampness is a factor in producing the disease. I remember reading in THE LANCET many years ago a letter from one whose name I forget pointing out a connexion between stable manure and diphtheria. Eight years' country practice in a district where the disease only occurred sporadically convinced me that after a flood had dried up, the disease was more rife than at other times. Seven years' suburban practice in a district that may be described as marsh land covered in convinced me still more that damp was the great *causa causans*. I am now living in flat land where vegetable refuse is supposed to be burned, but is not. On the contrary, it is put down dust shoots and thrown into small back-yards to fester and decay. In the streets at night there is a sour smell of decaying vegetable matter suggestive of an old-fashioned farmhouse pig-cistern. The district is frequently attacked by diphtheria. The solution of the problem contained in the first question seems to me to be $d + D = \Delta$, or in the vernacular, damp and decaying vegetable matter cause diphtheria. I believe that if bacteriologists will seek material in dust bins and decaying vegetable matter where cases of the disease occur, before long they will find the breeding-place of the diphtheria bacillus and we shall then have a complete answer to question No. 1. If this be right it should be noted that the increase of the disease coincides in date with the introduction of flats into London; I believe this was after the 1867 Paris Exhibition and a direct consequence of it. Dust shoots and bins ought to be abolished and all dust collected every day by the bucket system. I have known a dead dog to be put down a dust shoot here and be left for a week. I have ignored the

Digitized by Google

question of infection, as that is generally recognised, but would point out that cats must not be overlooked as carriers.

I am, Sirs, your faithfully,

VERE G. WEBB, L.R.C.P. Irel.

New Kent-road, S.E., Aug. 18th, 1897.

A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to state that I am not the Dr. Aveling who spoke at the Anarchist meeting in Trafalgar-square last Sunday?

I am, Sirs, yours faithfully,

CHARLES T. AVELING, M.S., M.D. Lond.

Cedar House, Stamford-hill, N., Aug. 25th, 1897.

UNQUALIFIED ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—The perennial question of the unqualified assistant has again elevated its head. Without raising the many vexed issues which have been argued with such acerbity I would venture to draw attention to one class of unqualified practitioners which has not received adequate notice. I am a medical practitioner living in a very highly rated parish in West London. If an accident occurs within a few yards of my door, and the victim falls into the hands of the police, he or she is at once "treated" in accordance either with the preconceived notions of surgery of the active and intelligent constable or with such knowledge as First Aid learning may have imparted. But it appears to be a canon with the force to avoid calling in qualified medical aid where by any possible means this can be done. Should any unfortunate result accrue to the patient no notice is taken of the fact that the preliminary treatment was applied not merely by an unqualified but by an amateur surgeon. If, on the other hand, the patient were brought to my surgery, and by any chance in my absence were to be attended by an unqualified assistant, skilful and as perfectly competent as many men in practice, and any mischance of whatever kind eventuated, an outcry would at once have been raised as to the employment of the unqualified assistant. There is also a further view of the case. Departmental ideas, whether local or otherwise, upon this subject do not always synchronise with the practice of the departments. To take a concrete case. On the Saturday preceding Bank Holiday my unqualified assistant saw a case which proved to be scarlet fever. He immediately referred the matter to me, and I, diagnosing the case, informed the parents that it required either isolation or removal to hospital, giving them, of course, the option, but informing them that in any case I must notify it. I notified it; but though I am to a certain extent anticipating, I may say that my notification, posted in due observance of the law on the Sunday, was received and opened only on Tuesday morning. In view of possible complications which might have arisen, and also in view of some which did arise recently in a somewhat similar case in which I was to a certain extent—by implication, at least—concerned, I took measures to have the case removed at once. The curious part of the whole matter is that the medical officer of health who took high ground recently when the unqualified assistant question was a feature in the case, but where his own department was proved to demonstration to be utterly and hopelessly in the wrong, has now left the professional work of his department to an *unqualified assistant*. Wanting information as to the propriety of notifying certain doubtful cases in connexion with a very high death-rate (about 70 per 1000), I was told I could not see the medical officer till his return from a six weeks' holiday, but I might see his chief clerk. I draw no inference. I enclose my card.

I am, Sirs, yours faithfully,

Aug. 24th, 1897. A QUALIFIED PRACTITIONER.

IT has been decided by the committee of management of the Westminster Hospital to entirely close their out-patients' department for the purpose of renovation and repairs, from Aug. 23rd to Sept. 18th, both days inclusive. The out-patient department of the Royal Free Hospital is also closed until Sept. 1st, and St. Mary's Hospital is entirely closed until the end of September

THE BRUSSELS INTERNATIONAL EXHIBITION.

(FROM A SPECIAL COMMISSIONER.)

WHAT with numerous congresses, the exhibition, and the fine weather, Brussels is crowded with visitors. The town looks all the more animated as the authorities have decorated the main streets leading to the exhibition with festoons, flags, banners, some gilt plaster statues, and coloured electric lights. Twice or three times a week there are illuminations. Under these circumstances it is not surprising that many persons have selected to spend a part of their holidays at Brussels. The exhibition is, of course, small when compared with the great international exhibitions of Paris, but it is large enough to thoroughly exhaust the visitor, especially if he desires to see everything in the course of two or three visits. It is large enough also to comprise an important section devoted to hygiene and a good many exhibits of surgical instruments and pharmaceutical products. The members of the profession, therefore, who visit Brussels may combine utility with pleasure, for they will find at the exhibition several things of technical interest. Unlike many other exhibitions, that of Brussels is of easy access. The town is admirably provided with a network of electric and ordinary trains, so that speaking generally the exhibition can be reached with little waiting or crowding and at but small expense.

On entering the grounds by turning to the right the visitor reaches the main building through a number of minor structures, which are, for the most part, cafés and restaurants, where, and also in contra-distinction to other exhibitions, meals can be obtained at moderate cost. Behind these there is a small oriental bazaar where the sounds of wild Arab music are to be heard and Moorish women dance. On the way to the main building there is also a separate and large circular structure, occupied exclusively by the French food section. Here may be seen how the French have imitated English biscuit manufactories, how the trade in preserved and tinned meats and vegetables has been developed, and there are also specimens of olive oil, wines, cognacs, &c.

Entering the main building by one of the smaller doors close at hand, and which is inscribed Bosnia and Herzegovina, the visitor is at once in the Austro-Hungarian section, and can note what care has been taken to develop these Serb provinces, now annexed by the Austrian Empire. On the walls large paintings give some idea of the beautiful scenery of these provinces, and show that they are likely to become favourite resorts for future tourists. Of the artistic products of Austrian industry—glass, pottery, carpets, furniture, and fancy articles—I need not speak. It is known that the *article de Paris* is often made in Vienna, and I allude to this section merely to say that the section of hygiene is situated immediately behind. The exhibits of the Ghent Bacteriological Institute deal principally with the analysis of meat and the bacteria found in some ham which had caused an epidemic in 1895. There are photographs of various animals taken after injections of an infusion of this meat. On the same spot the Belgian Temperance Society makes a brave show of sensational pictures and sections of the human liver so as to forcibly illustrate the evils of alcoholism. Then there are various models of masks to be worn by workmen engaged in dangerous industries, while the Belgian manufacturers of surgical instruments show how they apply antiseptic principles. For the operating-room furniture they seem to prefer copper or brass to nickel. Stools for the operating surgeons are made like piano stools, screwing up or down. The seat is a round concave sheet of brass, and the leg is partly brass and partly nickel. The tables, shelves, &c., are, of course, of plate-glass. To the operating table can be affixed a carefully cast copper seat that can be passed under the patient's back so as to raise the pelvic region while the subject is still lying down. The sanitarian will be interested to note in this section how Belgian manufacturers have imitated the well-known models of English drain-pipes, traps, &c., including methods for applying the smoke-test to household drains. There are also some Belgian pharmaceutical specialities and a carriage used by the Brussels town authorities for conveying the insane. It is in the shape of a small omnibus, and the front

Digitized by Google

part is divided into two padded compartments. The windows are of a special ground glass, of double thickness and unbreakable.

To the left of this section, close by, but walled off, are the extremely important and complete exhibits of the Ministry of Agriculture and Public Works. Here the Belgian Government show a model State laboratory and the measures taken for the enforcement of the various laws dealing with public health, and notably the prevention of the adulteration of food. To describe these exhibits would be to review the whole Belgian Legislature on the subject, and an entire volume might be written on such a topic. Fortunately there is a great deal of literature distributed here, so that the visitor can carry away with him the text of various laws, with details as to their application, so as to study them at his leisure. Thus, for instance, he can secure an official circular on the law of Nov. 18th, 1894, in which it is said that milk offered for sale must not be placed in leaden tins or metallic tins that have a lead alloy, such as certain forms of zinc. Article I. stipulates that milk from which cream has been removed must only be exposed for sale in receptacles bearing inscribed in large letters the words *lait écrémé*. The laws relating to beer, wine, meat, &c., are likewise set forth in printed circulars, which are at the disposal of the public, and thus visitors to the exhibition have a good opportunity of ascertaining what is the law on these subjects.

In the galleries that surround the vast hall devoted to machinery in motion there is another hygienic and social reform department. Here the French have a large demographical section with many charts and diagrams dealing with death-, birth-, and marriage-rates. Labour statistics, details as to charitable institutions, such as night asylums, *crèches*, &c., abound here. The French society for the better housing of the poor cover several partition walls with their drawings and plans. Other drawings, more especially connected with hygiene, illustrate plans and schemes for the draining and the water-supply of large towns. Among these I noted a scheme by M. Tusson, civil engineer, dealing with the town of Antwerp much on the lines which were indicated in the articles in THE LANCET on the cholera epidemic which prevailed a few years ago in that town. There is also a variety of drawings of public and private buildings which, though placed under the denomination of sanitation, are in reality of more interest to the architect than to the hygienist for most of these drawings contain no indication whatsoever of the methods of either ventilation or drainage it is proposed to employ. By far the best are the coloured drawings of the drainage scheme now in course of application to the town of Marseilles and those already mentioned, which it is proposed to apply to Antwerp. In both cases it is easy to see what is meant. In this gallery will also be found a vast exposition of diagrams and statistics setting forth the working of the workmen's compulsory insurance laws in Germany.

The military exhibits are very extensive, and several nations give specimens of field ambulances. The Red Cross Association of French Ladies has a large exhibit of its methods of training nurses and of providing help in cases of accidents and in the event of war. Among their equipment porous flannel shirts are in great demand, especially for the colonies. A convenient shirt for the wounded is also shown. This opens down one side and is fastened with tapes. No buttons are allowed, as it is sometimes difficult to fasten a button over a wound. All furniture is non-porous and easily pulled to pieces. Here also is a model of Dr. Gruby's tent. The metallic framework and the canvas weigh 2120 kilogrammes. The tent contains fourteen beds, and has two small separate compartments at each end. The Belgian Red Cross Society have established a working ambulance in a court close by. It is made by Messrs. Christopher and Unmack, of Copenhagen. The walls are of painted canvas stretched over a wooden framework. As there are two coatings of canvas the wall feels as if it were rather more than an inch thick. The separate rooms for the pharmacy and the surgeons are placed in the middle of the oblong tent. Thus the far end is well separated from the side where the sick or wounded are brought in. Three beds are ready in the event of any serious cases and the patients can be kept away from noise or disturbance in the further compartment. A nurse and medical men are in constant attendance, and of course there are stretchers and bearers at hand.

In another similar small inner court a variety of drain-pipes, gullies, and sections of sewers are exhibited; but I failed to notice anything new, though I did see several old and bad models. There are also numerous earth and peat closets with seats, which under the pretext of cleanliness seemed to realise the maximum of discomfort. Various filters are likewise shown here. In the main building, scattered in different directions, are different models of scaffolding, &c, devised in the hope of preventing accidents to workmen. Among these there is a ladder, "La Prévoyante" employed for window cleaning. Within the room it opens out and forms a letter V reversed; but if turned upside down two iron hooks enable the servant to hitch the point of angle made by the ladder to the window-sill. The steps of the ladder then protrude upward outside of the window and form a framework which prevents the window-cleaner from falling in the street. The Association of Belgian Manufacturers for the Prevention of Accidents have a model engineer shop worked by steam power and various styles of machinery all in motion, but so protected and guarded as to render accidents most unlikely if not impossible. This practical illustration of well-known theories is most interesting and to the point.

It cannot be said that the British section is very remarkable, at all events from the medical and sanitary point of view. Of course, there are the well-known tabloids of Messrs. Burroughs, Wellcome, and Co.; and considering the interest taken in Belgium in the colonisation of the Congo the adaptability of this form of pharmacy to tropical regions is well set forth. They have added some micro-photographs of cultures from their physiological laboratories and a general display of chemical substances used for pharmaceutical purposes. Close by Messrs. Ronald and Sérin, sanitary engineers, show how they apply Jennings' well-known sanitary apparatus to Belgian houses. John Dummock and Co. have also much enameled and porcelain sanitary hardware which is very elaborately decorated with floral designs.

In regard to education both in the French and Belgian sections there are many exhibits of interest. One in particular consists of a Belgian school of housekeeping, with a number of young girl pupils hard at work. Some are ironing, others are mending linen, and others are engaged at various household duties that all so largely contribute to maintain the comfort, happiness, and health of the home. This is a phase of education and a form of exhibit that greatly deserves encouragement. Of course there are numerous mineral waters and sanitary drinks to be found in different directions. Moreover, there is furniture for invalids, for field hospitals, and for tropical countries. In fact, it would be difficult to enumerate all that is of interest to the medical practitioner and to the sanitary reformer. Enough, perhaps, has been said to make it manifest that there is something to be learnt by a visit to the Brussels exhibition. As the means of communication are easy, the journey from England short and inexpensive, and life in Brussels is cheap and pleasant, there can be but little doubt that many persons will be tempted to avail themselves of these facilities and inducements.

Brussels, Aug. 15th.

PROFESSIONAL PROSPECTS IN ITALY.

(FROM A CORRESPONDENT.)

As a place of resort for the invalid or convalescent the future may well-nigh be said to belong to Italy. She has numberless sun-traps with marine or mountain exposure in winter; she has delightful airing grounds in the Apennines and on her sub-alpine slopes during summer; while her spring and autumn, particularly the months of May and October, are as nearly perfect for the robust or the weakly alike as are to be had in the temperate zone. Add to this that she is exceptionally rich in mineral waters, mud-baths, and thermal springs, and the result is an *ensemble* of conditions that put her at a singular advantage over other nations of Europe. Of her other attractions for the votary of art, literature, and even science there is no need now to speak.

But she has tremendous lee-way to make up before civilisation can reap the full benefit of those advantages and before she herself can draw from them the pecuniary return she requires so sorely. Out of the beat of tourist resort she

Digitized by Google

is little better than mediæval in hotel accommodation, appointments, and *cuisine*; while even at her recognised and frequented health resorts she is so far behind trans-alpine Europe that the superiority she owes to nature over her rivals is more than neutralised by the defective conditions referred to.

Still she is making progress in many ways, and the next century cannot be much beyond its teens before she has put herself level with contemporary civilisation.

One stimulating element in this direction is the presence of the English-speaking world and the representatives of English-speaking practice in her midst. By the admission of her more competent and most candid public men of all professions, she owes much to the object-lessons in civilisation imported especially from the British empire. To minimise or even materially to reduce that invigorating and refining influence, it might be thought, would be the last thing her legislature should attempt. And yet, if an agitation now proceeding in her professional circles and already making itself felt in her parliament takes practical effect, she will do herself the great injury of deterring the English-speaking world from visiting her shores, and with it all the influences, refining and invigorating, just indicated.

The agitation in question concentrates itself in the so-called Santini Bill for excluding English-speaking practitioners from the English-speaking world, resident or migratory, she annually receives. That measure, already in its initial stages before the Camera dei Deputati, has frequently been commented on in the columns of THE LANCET, and the later, maturer opinions formed of it inside and outside the profession are not favourable to its becoming law. Signor Serena, Under Secretary of State in the Department of Grace and Justice, in his replies to Dr. Santini's interpellations, seems unwilling to commit the Government to more than to the exclusion of English-speaking practitioners from Italian *clientèles*. He has no objection to the continuance of the existing arrangement by which the English-speaking world shall have the power of calling in compatriot medical advice. In other words, he is by no means inclined to make Italy follow the ungracious lead of Switzerland and France, and render it impossible for English-speaking patients to avail themselves of English-speaking consultants.

This is as it should be, but it remains to be seen whether the Di Rudini administration adheres to the enlightened policy embodied in Signor Serena's replies, or whether it will yield to the pressure under which all Italian ministries are apt to become pliable. For one thing, Signor Serena seems to have mastered the situation so far as to appreciate the active and powerful opposition the Bill will encounter from the commercial, the hotel-keeping, the railway, and similar interests, deriving, as these do, so essential a part of their revenue from the English-speaking visitors and residents. Meanwhile, as matters stand, Italy remains a tempting field for the young British or American practitioner. Indeed, the presence of such a duly qualified medical adviser is often of itself sufficient to determine the tourist or valetudinarian public to resorts having every other attraction that nature can vouchsafe. A case in point is that of Sicily, whose recommendations as a winter residence for the weakly or the ailing, often vaguely surmised, have now been beyond cavil established in the columns of THE LANCET. The accommodation demanded by the civilised world and the presence of such practitioners as the British-American schools annually produce alone seem wanting to redeem that "island of Prospero" from the financial and other straits she has so long laboured under. And what is true of Sicily is true of Italy as a whole.

LITERARY INTELLIGENCE.—Messrs. J. and A. Churchill announce that they have recently published the sixth edition of "The Theory and Practice of Surgery," by W. J. Walsham. The book has been increased by 50 pages, though the price remains the same. Other new editions just ready include the third of Hartridge's Ophthalmoscope and the fourth of Clowes' and Coleman's Quantitative Analysis.—The Rebman Publishing Company, Limited, London, and Mr. W. B. Saunders, Philadelphia, will issue shortly an entirely new work on "The Diseases of Women," written for students and practitioners by Mr. J. Bland Sutton and Dr. Arthur E. Giles. The book will be profusely illustrated with woodcuts, most of which have been drawn expressly for it.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Sewage Again.

THE continued recurrence of the sewage question, the stringent but justifiable requirements of the Mersey and Irwell Joint Committee, the pitiful position of the Manchester Corporation, distracted by ever-varying counsels, which sometimes advise one course and then urge another, have by this time become familiar and probably wearisome to those who take any interest in municipal or sanitary questions. A short time ago artificial filtration seemed to be in favour as against the scheme of a culvert to the estuary of the Mersey, but the annual cost of the working, and the renewal of the filters every three or four years, would involve an estimated annual outlay of £31,820, to which the majority of the Rivers Committee of the corporation are opposed, and a sub-committee unanimously decided to recommend to the Rivers Committee that the effluent, after chemical treatment, should be taken to the tidal waters of the Mersey. This means that the Ship Canal will be deprived of the six or eight million gallons of purified effluent which should flow into it daily. In the meantime, the period of a year allowed by His Honour Judge Parry to the corporation for the preparation of a scheme having almost expired, the corporation asked for six months more grace, and have been granted three months. While all this time is being spent the river and the Ship Canal remain in a condition so foul and disgusting as to be a disgrace to a civilised people. Unfortunately, however, civilised people, so-called, do not appear to care about some of their surroundings more than, if so much as, many so-called savages, for where chemical industry and the mechanical arts are found the streams are invariably polluted and filthy.

Libel by an Insane Patient.

Mr. Mould, the superintendent of the Cheadle Asylum, has recently been the subject of libellous proceedings on the part of a former patient, who was brought up on remand before Mr. Headlam, the Manchester stipendiary, on the 18th inst. for publishing libels on Mr. Mould. Such an occurrence is one of the amenities to which superintendents of asylums sometimes become accustomed. In this case he was associated with Mr. Harley, the postmaster of Manchester, and Mr. Malcolm Wood, the chief constable of the city. The defendant said, as usual, that he was perfectly sane and the victim of a foul conspiracy, and proceeded with an excited harangue. In the end the poor fellow had to be removed and was afterwards conveyed to an asylum.

The Food Question in Workhouses.

A discussion took place at the meeting of the Prestwich guardians on the 19th inst. on a resolution proposing that an inquiry should be made as to the waste of food, if any, at the workhouse and the manner in which it is served. The chairman said that by the regulations of the Local Government Board the food had to be weighed and a certain quantity served to each inmate. One of the guardians instanced the Chorlton Workhouse, where "tons of bread were wasted at table," and the Local Government Board refused to sanction a system by which this might be avoided. The resolution was adopted.—At the meeting of the Chorlton guardians on the 20th inst. the chairman, Dr. J. M. Rhodes, alluded to the statements made at the meeting of the Prestwich board, and said they were carrying out the system started four months ago and did not intend to alter it. The Local Government Board had difficulties. There were some boards of guardians "whose main object seemed to be to screw expenses down and where there were workhouse masters bent on a stringent policy." It may be hoped, however, that the experiences of Oliver Twist could not now be repeated in the most unsympathetically managed workhouse in the kingdom. Dr. Rhodes also stated that the Local Government auditors found that the new system was less costly than the old, and that the Board was coming round to their view. He believed "that the system they had inaugurated benefited both the ratepayers and the poor" where the departments were under the management of well-paid and efficient officers.

Singular Death.

A washerwoman, aged twenty-five years, living at Weaste, was washing some blankets on the 5th inst. and wished to use

Digitized by Google

some ammonia. Having some difficulty in drawing the cork she got hold of it with her teeth. It came out suddenly and a quantity of the liquid went into her mouth. She was taken to the Salford Hospital, but died early on the morning of the 9th inst.

Aug. 24th.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Proposed Convalescent Hospital for Bristol.

MR J. S. FRY, who had previously subscribed £3000 towards the proposed Convalescent Home for Bristol, has promised to substitute for this an offer of £10,000, provided that £40,000 is raised before Dec. 1st. Sir W. H. Wills has offered to increase his original contribution of £1000 to £5000 with the same stipulations. The balance now required to render the institution self-supporting is £13,000, and doubtless a strong effort will be made to secure these generous donations.

The Bristol General Hospital.

A sum of £1500 has been given by an anonymous donor to the Bristol General Hospital to be devoted towards defraying the cost of the enlargement and reconstruction of the laundry. Since the recent extension of the hospital the laundry and kitchens have been found to be inadequate. The proposed alterations will cost more than the £1500, but it is hoped that other subscriptions will be received.

A Nuisance at Merthyr.

At Merthyr Tydvil police-court on Aug. 9th the proprietor of a candle factory at Caedraw, Merthyr, was summoned for carrying on his business in such a way as to be injurious to the public health. It was complained that the pipe leading from the vat used for melting the fat was in a defective state, and that the shaft into which it was carried was insufficiently high, the result being that noxious smells were emitted. The Bench held that the defendant had not carried on his business with proper care and imposed a fine of £5 and costs.

"Prejudice against the Doctor."

At the last meeting of the Yeovil Board of Guardians Mr. A. W. Sinclair, L.R.C.P. & S. Edin., the surgeon for the South Petherton district, attended and gave an explanation with reference to a complaint made to a lady guardian for South Petherton by the mother of a boy who had recently fractured his leg. It was stated that the medical officer had only visited the lad on three occasions. Mr. Sinclair said that the whole story of his neglect was a fabrication, and proved from the entries in his visiting list that he had attended the boy almost daily until he was removed to the hospital. Mr. Sinclair stated that it was exceedingly disagreeable to him for guardians to show such animus towards him whilst residing in his district, and added that this was the second time he had been accused of falsehood. The board did not think a further statement from Mr. Sinclair was necessary, and passed a resolution stating that there was not sufficient evidence in the case. The Rev. W. D. Armstrong, who strongly supported this, said that he ventured to think there was "some sort of prejudice against the doctor." Mr. Sinclair is to be congratulated on the result of this inquiry, and for the future it is to be hoped that such groundless complaints will not be made by any of the guardians.

Aug. 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Visit of the Duke and Duchess of York.

THE visit of the Duke and Duchess of York to Ireland is obviously much appreciated by a large proportion of the population, their Royal Highnesses having been everywhere enthusiastically received. On the 20th inst. addresses were presented to His Royal Highness by the Presidents of the Royal Colleges of Physicians and Surgeons respectively. Sir George Duffey, the President of the Royal College of Physicians, who was accompanied by Dr. Wallace Beatty, Dr. Lombe Atthill, Dr. James Craig, Sir John Banks, Physician-in-Ordinary to the Queen in Ireland, and Dr. William Moore, Physician-in-Ordinary to the Queen in Ireland, read the following address of the Royal College of Physicians:—

"TO HIS ROYAL HIGHNESS, GEORGE FREDERICK ERNEST ALBERT, DUKE OF YORK, EARL OF INVERNESS, AND BARON KILLARNEY.

"MAY IT PLEASE YOUR ROYAL HIGHNESS,—

"We, the President and Fellows of the Royal College of Physicians of Ireland, on the occasion of your present visit to this country beg to offer to your Royal Highness a hearty welcome to Ireland, and a renewed expression of our devoted loyalty and attachment to her most gracious Majesty the Queen.

"We would also assure you of the great gratification we feel that you have been pleased to honour Dublin with your presence at so memorable a time as this, when we have been celebrating the completion of the sixtieth year of the Queen's reign.

"We desire also most respectfully to express our satisfaction that you are accompanied by her Royal Highness the Duchess of York, sharing as we do most warmly in the feeling of attachment with which all loyal citizens welcome the visit of members of a Royal Family so universally and justly beloved.

"Signed on behalf of the College.

"GEORGE F. DUFFEY, M.D., Knt., President.
"JAMES CRAIG, M.D., Registrar."

Sir William Thomson, the President of the Royal College of Surgeons, read the following address on behalf of that body. He was accompanied by Dr. A H. Jacob, Mr. Henry Gray Croly, Mr. W. I. Wheeler, Sir Thornley Stoker, and Mr. H. R. Swanzy:—

"TO HIS ROYAL HIGHNESS, GEORGE FREDERICK ERNEST ALBERT, DUKE OF YORK, K.G.

"MAY IT PLEASE YOUR ROYAL HIGHNESS,—

"We, the President, Vice-President, and Council of the Royal College of Surgeons in Ireland, beg most respectfully to offer to your Royal Highness and to the Duchess of York a cordial welcome on the occasion of your visit to our country.

"As a member of the family of Her Majesty, our revered Queen, and as the lineal representative of their Royal Highnesses the Prince of Wales and the Princess of Wales, your advent to Ireland affords us great satisfaction, and will, we believe, be received as a manifestation of your desire to acquire that personal knowledge of Her Majesty's Irish subjects which can only be obtained by direct observation. We are convinced that frequent association of your Royal Highness and other members of the Royal Family with our people will be attended by the most beneficial results by confirming and increasing the attachment of this country to the Throne and by maintaining in the Royal Family a warm interest in the prosperity of Ireland.

"We beg further to assure your Royal Highness of the determination of our College to aid in maintaining in the future as in the past those loyal and dutiful relations with Her Majesty and her august Family which have hitherto existed.

(Signed) "WILLIAM THOMSON, President.
"ROBERT L. SWAN, Vice-President.
"CHARLES CAMERON, Secretary of the College.
"ROBERT H. WOODS, Secretary of Council.
"GEORGE F. BLAKE, Registrar."

The Mater Infirmorum Hospital, Belfast.

The Belfast and County Down Railway Company, at their half-yearly meeting, held on Aug. 10th, agreed to subscribe £200 out of the revenue of the company, to the fund for the erection of the Mater Infirmorum Hospital.

Belfast District Lunatic Asylum.

Dr. William Graham, medical superintendent of Armagh Asylum, has been transferred by the Lord-Lieutenant to the Belfast District Lunatic Asylum, as successor to Dr. Merrick (resigned). Mr. George Lawless, of the Sligo Asylum, has been appointed to Armagh.

Kilkeel Dispensary.

Dr. Floyd was, on Aug. 24th, unanimously elected medical officer of Kilkeel Dispensary, No. 1 district, in place of Mr. Gordon, resigned.

Belfast Royal Hospital.

At the quarterly meeting, held on Aug. 23rd, it was reported that during the past three months there had been 539 intern and 6690 extern patients. At the close of the previous quarter the debt against the hospital was £2624 13*s.* 9*d.* Since then the receipts have been £1704 19*s.* 11*d.*, and the expenditure £2298 15*s.*, which brings the indebtedness to a sum of £3218 8*s.* 10*d.* at the end of July. This large sum owing by the hospital is to be accounted for to a considerable extent in an expenditure on necessary alterations in the house, and a sum of £2500 was voted to meet this indebtedness, which, when realised, will bring the actual debt down to £718 8*s.* 10*d.* Professor Cuming, M.D. R.U.I., was re-elected staff-physician.

Untrained Nurses in Union Hospitals.

Pauper nursing in union hospitals has recently been the subject of much comment, and at the last meeting of the Kilrush guardians the medical officer, Dr. Foley, strongly urged the appointment of properly trained nurses. In the course of the discussion which ensued Dr. Foley gave the

Digitized by Google

following forcible description of the evils likely to result from entrusting the care of the poor patients to unpaid pauper attendants: "The pauper helpers receive more kicks than halfpence, and any work they do has to be squeezed out of them. It is not human nature to expect under the circumstances that they will show feeling and consideration to the inmates. Besides, their misfortunes sour their dispositions. Then they levy blackmail, and the patient who does not give a few pence is certain to be neglected." The guardians were evidently impressed by their medical officer's representations, and decided on holding a special meeting for the purpose of considering the question in all its bearings.

Vaccination in the Kenmare Union.

At the last meeting of the Kenmare board of guardians Dr. Browne, Local Government Board inspector, complained of the very backward state of vaccination in the union, and he said that he had learned from the dispensary medical officers that this was due to the fact that the guardians declined to enforce the law to compel parents to comply with the provisions of the Compulsory Vaccination Act. In reply one of the guardians explained that the great majority of the board objected to the system of vaccination from arm to arm, but that they would be prepared to carry out the law if lymph taken directly from the calf were used. A discussion ensued, and Dr. Browne announced that calf lymph could be procured by the union medical officers whenever the parents of children so desired.

PARIS

(FROM OUR OWN CORRESPONDENT.)

Anti-choleraic Serum.

M. GAUTHIER laid before the Academy of Medicine on behalf of Dr. Ferran, of Barcelona, a claim of priority with respect to the treatment of cholera by anti-choleraic inoculations—a treatment the good effects of which the medical faculty in Spain as well as the public experienced in 1889. MM. Brouardel and Bertrand observed that the methods of the Spanish medical man, which date from 1885, the date when a commission of French medical men visited him for the purpose of investigation, did not at that time by any means give the beneficial results which their author claims for them to-day. On the other side, Dr. Ferran refused in 1885 to give up the formula of the composition of his vaccine, and has continued to persist in this refusal. Under these conditions the Academy has declared that it can neither give any decision as to the curative virtues of a preparation of which it knows nothing, nor give any support to Dr. Ferran in his claim for priority.

Isometropic Lenses of Baryta Glass.

For some time past so-called isometropic lenses made of baryta glass for spectacles have been used in Paris, which are said to be better for the sight because their curvature is less than that of ordinary lenses of the same focus. MM. Druault and Tscherning have examined these lenses in the ophthalmological laboratory of the Sorbonne, and have decided that they are very inferior to lenses made of ordinary glass. Their index of refraction is higher—namely, 1·576 instead of 1·534—and the difference of curvature is about 8 per cent., which is of no practical advantage. The baryta lenses are no harder than those of ordinary glass; they are slightly more transparent, but they have no other advantages.

Floating Hospitals.

Dr. Burot, Professor at the Naval School of Medicine, has just published the results of an inquiry into the working of hospital ships. During the late Madagascar expedition an interesting trial of hospital ships was made, the results of which merit every recognition. These results were very good, says Dr. Burot, and hospital ships are undoubtedly destined to render very valuable services in colonial expeditions. The *Shamrock* was the name of the ship which was employed on this service in 1895, and, according to Dr. Burot, all the sick soldiers were most anxious to be sent on board, and the greater part of them considered themselves quite safe as soon as they saw their names on the list for removal. There were only sixty deaths out of a total of two thousand sick. Counting the period of service of this ship at six months, this number works out at ten deaths per month, a mortality of 3 per cent., and one very much lower than that which existed during the same time in the hospitals in Madagascar. It is also a great deal lower than that of the hospitals either at Toulon or Saint Mandrier.

French Scientific Congresses.

The Congress of the French Association for the Advancement of Science has just taken place at St. Étienne. The question of actinomycosis brought out some very remarkable researches, especially those of MM. Poncet and Bérard.—A meeting of French alienists and neurologists has been held at Toulouse to consider the question of general paralysis and the organisation of the medical service of lunatic asylums.

Drinking-water in Paris.

Every speaker, whether in the Chamber or in the Senate, during the recent discussion declaring the intended works for utilising the Loing and the Lunain as a source of water-supply to be of public importance, has called the attention of the Prefect of the Seine to the insufficiency of the supply of drinking-water to Paris. This supply, which sometimes rises to 240,000 cubic metres for a population of 2,500,000 within the walls, fell to 197,000 cubic metres during the drought in 1895, so that it was necessary to supply certain quarters with water from the Seine, a most unsatisfactory proceeding. The Prefect of the Seine, M. de Selves, has therefore determined to study the methods of meeting the present evils, and with the assistance of all the leading exponents of science has started a commission to examine the various questions which arise as to the supply of Paris and its suburbs with a good drinking-water.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The New Tuberculin.

THE recent numbers of the *Deutsche Medicinische Wochenschrift* contain further instalments of the articles on the new tuberculin, some account of which has already been given in THE LANCET.[1] In the children's department of the Charité Hospital, Berlin, the remedy was tried in five cases, reported by Dr. Slawyk, assistant physician to that hospital. One child was given twenty-three injections, one was given twenty-one, and three children were given two. The smallest quantity injected was $\frac{1}{10\,000}$ milligramme of tuberculin, and the largest was six milligrammes. The injections were performed strictly in accordance with Professor Koch's directions. One child, a boy, aged eight years and nine months, suffered from marked scrofulosis, the symptoms being swelling of the cervical and submaxillary glands, cicatrices on both sides of the neck, blepharitis, swelling of the abdomen, chronic catarrh of the right lung, and enlargement of the liver and spleen; there was, however, no fever. The injections, although they did not at first exceed the small dose mentioned above ($\frac{1}{10\,000}$ milligramme), were, as a rule, followed by severe reactions—rise of temperature to 39 6° C. (103·3° F.), profuse perspiration, collapse, and hyperæmia at the place of the injection. It was also noticed that the sites of former injections became swollen when a new injection was made. The reaction, as a rule, began on the day of the injection; it often continued for several days, and was not liable to be attended by troublesome symptoms, notwithstanding the high temperatures. An alarming collapse, however, occurred in one case, the last injection (of six milligrammes of tuberculin) having been given twenty-two hours previously; the child became unconscious, the colour of his face was livid, the respiration stertorous, and the pulse weak. In the evening, about thirty hours after the injection, the collapse had reached its maximum, the respirations being 96 per minute and the pulse 186. During the night the child's state improved and about noon next day the danger was over. The injections were of course no longer continued with this patient. This untoward occurrence could not be attributed to the manner in which the operation was performed; probably the dose was too large for a child of that age. Another child, aged eight years, who suffered from pulmonary tuberculosis, together with symptoms of scrofulosis, had a more favourable experience than the child just mentioned; febrile reaction only happened after the last injections and in

[1] THE LANCET, July 17th, 1897, p. 171.

Digitized by Google

a slighter degree. With regard to the curative influence of the injections the report states that in the last case the objective symptoms in the lungs had diminished; in the first case the swelling of the glands also decreased during the treatment — Dr. Wörner, physician to the hospital of Schwäbisch-Gmünd (Würtemberg), has used the tuberculin on eight patients, four of whom suffered from lupus, one from scrofulosis, and three from pulmonary tuberculosis. He recommends that the dose of the tuberculin should be increased very slowly—about 0·002 or 0·005 milligramme every second day. In this way febrile reaction may be avoided. In his experience unpleasant symptoms occurred in only one case and were apparently due to the tuberculin being of too high activity. The bottle was sent out by the Hoechst factory on the same date as that which had caused the severe symptoms in the case under the care of Dr. Bussenius in the Charité Hospital of Berlin.[2] Apparently the degree of virulence of the individual samples is apt to vary a good deal. Of the cases of lupus one patient who had for a long time suffered from the disease is nearly cured; two who had been operated on some time before the injections have had no relapse, and the patient suffering from scrofulosis is nearly cured. The effects on pulmonary tuberculosis have not hitherto been obvious enough to be recorded; there is, however, no indication of the treatment disagreeing with the patients.—A very interesting case of tuberculosis of the genital organs is described by Dr. Seeligmann, of Hamburg. A woman, twenty-eight years of age, suffering from lupus of the nose, complained also of menstrual troubles, and double pyosalpinx was found together with ulcerations in the vagina. The vaginal secretion contained tubercle bacilli. After forty injections there was a great change for the better in the patient's condition; menstruation was regular, the lupus of the nose was healed, the enlargement due to the pyosalpinx had disappeared, and tubercle bacilli were no longer discovered in the vagina.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Health of the Pope.

THE "mythopœic spirit," so familiar to the student of the past, is not less *en évidence* in the present; witness the inventions and fabrications that figure as "news" regarding the thoughts and actions, even the physical condition, of leaders in the contemporary world. Probably no personage gives such occasion for its exercise as the Supreme-Pontiff, whose "health" inspires so much solicitude in continental journals that hardly a fortnight passes without their commenting on it. I read, for instance, in an influential organ of the Alta Italia that "on the evening of the 16th inst. the Holy Father had two fainting fits (*svenimenti*), which recurred with equal gravity on the morning of the 17th. Professor Ceccarelli never leaves the Vatican so as always to be in attendance on Leo XIII. There is much anxiety in Rome," adds the chronicler who telegraphs the "news" from that city, "on account of this intelligence." Having read an obituary notice of the self-same distinguished Professor Ceccarelli in THE LANCET some five years ago[3] my scepticism as to the authenticity of the "intelligence" was rather more accentuated than usual, so I thought I would inquire at the only quarter whence information as to His Holiness can be obtained at first hand. I received for answer, "Il Papa sta benissimo" (The Pope is very well indeed); followed by the request, "Smentite la voce che il Papa fosse ammalato, tanto che il medico del Pontefice ricevette dispacci dalla Francia e dalla Germania che chiedevano notizie" (Contradict the rumour that the Pope was so ill that the pontifical physician received telegrams from France and Germany asking for particulars). That "counter" to which so many untruths are "nailed" would need to be of illimitable expansion!

Honours to Professor Sanarelli.

Siena is naturally proud of the alumnus whose discovery of the microbe of yellow fever has put the study of that tropical scourge on so advantageous a footing for its prophylaxis and clinical treatment, and the ex-rector of her school, Professor Domenico Barduzzi, still one of the most respected of her medical staff, in whose clinique young Sanarelli was trained, has expressed the mind of his colleagues in the following inscription, on the lines of which another will be inscribed on a memorial tablet to be unveiled in Sanarelli's honour on the university walls:—

GIUSEPPE SANARELLI—discepolo valoroso, maestro preclaro—nell' Ateneo Senese—giovane di anni, maturo di studi severi—fondatore dell' Istituto di igiene sperimentale—in Montevideo—svelando sulle rive del Plata—fra disagi, ansie, pericoli—il germe insidioso violento della febbre gialla—apriva nuova sicura mirabile via—contro tanto flagello.—All' amico, al collega carissimo—Domenico Barduzzi—manda plaudente fervidi auguri—di altre conquiste per la vita umana, per la scienza—di nuovi imperituri trionfi per l'Italia.

Siena, luglio MDCCCXCVII.

(To Giuseppe Sanarelli, a pupil of power, a teacher of distinction in the Sienese University; young in years, mature in severe study; founder of the Institute of Experimental Hygiene in Montevideo; disclosing, on the banks of the Plata, amid difficulties, anxieties, and dangers, the insidious yet violent germ of yellow fever, and opening up a new way, as secure as it is wonderful, to combat so formidable a scourge—to the well-beloved friend and colleague, Domenico Barduzzi sends with applause his ardent auguries of yet other conquests for human life and science and of fresh, immortal triumphs for Italy. Siena, July, MDCCCXCVII.)

A "Serum Anti bubonicum."

The event of the day in professional circles is the return of the Florentine bacteriologists from Bombay, whither the Di Rudini Ministry sent them to try to discover a prophylactic serum against the "pestis bubonica." These gentlemen, all from Florence—Professor Lustig, Dr. Malenchini, and Dr. Galeotti—received from the Bombay Government every encouragement and every facility in their researches; and their findings and conclusions, embodied in a report shortly to be made public, are stated to be eminently satisfactory. The Lustig serum, as it is called, differs from that of Yersin in being not curative but preventive; it belongs not to clinical but to State medicine. In its preparation, moreover, it offers much fewer difficulties than Yersin's. It is absolutely free from bacteria, it is dry, and, what is of capital importance, its effects on man and beast are quite harmless. Inoculated under the skin in small doses dissolved in water alkalinised and sterilised, it produces only a slight local œdema, which disappears in twenty-four hours. Tested repeatedly on rats, guinea-pigs, horses, and apes, the serum (particularly in the case of horses) had, in Professor Lustig's language, "risultati rapidi e soddisfacenti" (results speedy and satisfactory). Nor did the experiments stop with the lower animals. Professor Lustig, Dr. Malenchini, and Dr. Galeotti made trial of the serum on their own persons, and with gratifying effect. Further investigations confirmed the value of the "vaccino preventivo," as the report designates it; so that, unless three of Italy's most accomplished bacteriologists have been misled by some unforeseen source of error or some undetected fallacy they may be congratulated on having added a defensive weapon to State medicine in a quarter where it has long been desiderated.

Cholera Shadows.

On board the same peninsular liner, the *Britannia*, that landed Professor Lustig and his colleagues at Brindisi occurred two cases of cholera which caused some detention in that port before "*libera pratica*" (free course) was obtained. The disease declared itself in the Red Sea, and the patients were made to disembark at Suez, together with those in attendance, and were all of them placed under surveillance at the International Sanitary Station at the Wells of Moses. The steamship was thereafter allowed to traverse the Suez Canal in quarantine. The brevity of the interval between the disembarkation of the cholera patients and the arrival at Brindisi is held to justify the Italian Government in forbidding at the latter port the landing of the passengers and goods till the certificate of "*libera pratica*" could be granted.

Aug. 23rd.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The late Professor Joseph Kovács.

BUDAPEST University has received a heavy blow by the death of Professor Kovács, who succumbed to diabetes on

[2] THE LANCET, July 17th, 1897, p. 172.
[3] THE LANCET, Feb. 25th, 1893.

Digitized by Google

Aug. 6th, in his sixty-fifth year. When he was only sixteen years of age Kossuth roused the Hungarians against their Austrian rulers, whereupon he left college and served in the army which fought for the liberty of the country. After the revolution he continued his studies in Budapest and Vienna, and having received the degree of M.D. he soon became the assistant of Dr. Balassa, then Professor of Surgery in the Budapest Medical Faculty. At the age of thirty years he was appointed Lecturer on Surgery. During the Austro-Prussian war in 1866 he was entrusted with the surgical treatment of the wounded who had been removed to Budapest, and he executed this difficult task with great credit to himself and satisfaction to the profession. In 1868 he was appointed to the ordinary Professorship of Surgery, which he held until his death. He was also adviser to the Minister of Public Instruction. The name of Professor Kovács was little known in the medical world outside Austria-Hungary, but those who had the good fortune to witness his extraordinary skill in performing operations or to listen to his teaching at the bedside were all aware that he was not only an accomplished surgeon but a keen observer and a clear-headed man, possessing a sound and well-balanced judgment. He had the great merit of having trained in this country a number of surgeons who now occupy responsible posts and are celebrated for the ability which characterises their work. The memory of Professor Kovács will long be cherished, both by his pupils and by all who have known him.

Aug. 16th.

Obituary.

WILLIAM JOHN PILCHER, F.R.C.S. ENG., L.A.H. DUB., J.P.

GENERAL and sincere regret has been caused in South Lincolnshire by the announcement of the death of Mr. Pilcher, one of the best-known residents in Boston. His last illness was of about a fortnight's duration, and he died at his residence in the High-street on Aug. 16th. Mr. Pilcher was born in Antigua in 1837. He studied medicine in Dublin University and in the schools attached to the Royal College of Surgeons in Ireland, becoming qualified as L.A.H. in 1858, L.M. (Rotunda Hospital) in 1859, and M.R.C.S. Eng. in 1860. His first professional engagement was as surgeon on board a Cunard mail steamer. In 1863 he settled in Boston, where he acquired an extensive practice and took an active part in the social and public life of the town. Mr. Pilcher was admitted to the Fellowship of the Royal College of Surgeons of England in 1869. His professional attainments were of a high order and the soundness of his judgment was generally recognised. He was one of the founders of the Boston Hospital, which dates from 1871, and has grown to its present size from a very small beginning, the patients having been at first accommodated in two cottages in Irby-street; its prosperity caused him the greatest satisfaction, and at the time of his death he was the oldest member of its medical staff. He was also a medical officer of the Boston Provident Dispensary, and had been President of the Midland Branch of the British Medical Association. He was made a Justice of the Peace for Boston in 1873; under the last Liberal Government he was also appointed a Justice of the Peace for the county, but he did not proceed to full qualification for this latter office, and never took his seat. Owing to the esteem in which he was held by his fellow townsmen he was chosen to fill various positions of local importance, being chairman of the Steam Laundry Company, deputy chairman of the Deep Sea Fishing and Ice Company, a charity trustee for Boston, and a trustee of the Parry Scholarship and Gold Medal. He also took a prominent part in connexion with the organisation of the University Extension lectures and the Gilchrist Trust lectures in Boston during 1895 and 1896. In November, 1895, he was elected an alderman by the town council. The funeral took place in Boston Cemetery on Aug. 18th in presence of a very large assemblage and amid general tokens of public mourning.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

MOSCOW, AUG. 19TH—26TH.

THE Twelfth International Medical Congress, held under the "high protection" of His Imperial Majesty the Emperor Nicholas II. and the "august patronage" of His Imperial Highness the Grand Duke Sergé, was formally opened by the Grand Duke at Moscow on Thursday, Aug. 19th, 1897. We shall be pardoned by our readers if we explain that in Russia there is official usage of what is called "old style" in the matter of dates; therefore in Moscow the Congress is held to have been opened on Aug. 7th, the "old style" being twelve days behind the rest of Europe.

Moscow, the wonderful many-coloured capital of ancient Muscovy, was looking its best on the opening day, and its best almost defies description. The painted towers, the gilded domes, the quaint spires, the old cathedrals, the new public buildings, the palaces, the shrines, and the hovels, each have their individuality and combine to make a whole the general effect of which cannot conceivably be summed up in a phrase or two. Brilliant colour seen against sober neutrality, civilisation, if not in all its most convenient forms, certainly in many of its hyperæsthetic developments, nodding to barbaric simplicity, palaces of the fourteenth century contiguous to seminaries of the nineteenth, the East arm-in-arm with the West,—these things make up a medley which can be imagined but hardly described.

The city is very full, but the English-speaking visitors are in a minority. There is no doubt that the lack of early organisation on the part of the Executive Committee of the Congress led to the abstention of many visitors, and particularly of many who had to come from a very long distance. Some who had paid their money and had been enrolled as members did not care to venture so far East without receiving any definite response to their requests for information as to lodgings or hotel accommodation. Others did not obtain acknowledgment of their cheques and their railway passes sufficiently early to enable them to arrange to make Moscow the seat of their usual summer holiday. "We who are in Moscow, however," writes one of our Special Correspondents, "can testify to the cordiality of our reception, but so full is the city that we are selfish enough not to be sorry that England is so badly represented."

The Germans have turned up in enormous numbers, and, as has been observed at these Congresses before, they all seem to know each other. The large hotel, the Slaviansky Bazar, and the enormous restaurant contiguous to it, are both the constant scene of big reunions of bearded savants, who all greet each other with an effusion that would go far to show that professional jealousy has not any abiding-place in the German empire. To other members of Congress there is present occasionally a certain anxiety about their ignorance of Russian customs and language, but into the German breast such apprehensions do not seem to enter. With one accord they seem to have decided that the Congress offers an opportunity to them for a picnic and a renewal of their student friendships.

We allude to Moscow advisedly as the capital of Russia, for this it is although the official Government has its seat in St. Petersburg. But round Moscow the real Russian tradition clings. Here we have the holiest fanes, and

Digitized by Google

here, in the famous Kremlin, are the ancient documents which tell the story of the evolution of the empire. Geographically, also, Moscow is the centre of the present Russian empire, and in whichever direction, if any, the territorial expansion occurs Moscow will be the focus of all business organisation, being in touch alike with Siberia and Tartary, with Finland and the Crimea. But whether Moscow is an ideal place for a medical congress is another question. It is a difficult city to reach, and when reached it has but indifferent accommodation to offer to the visitor. There are few hotels, and only one of any size, while the use of *Meblivoranni Komnatie*, or large blocks of furnished apartments under the supervision of a landlady, is not one into which the ordinary traveller quickly falls. Let us hasten to add that every attempt has been made on the part of the organisers of the Congress to make the visitors comfortable and to avoid the annoyance and inconveniences of arrival in a strange city; but Moscow does not lend itself to the sudden addition of 7000 persons belonging to what in Russia are the upper classes within a few hours. Consequently, we know that many visitors to the Congress have been very uncomfortable, while the impossibility of explaining their wants to a population which speaks for all practical purposes nothing but Russian has added to their troubles.

The Congress informally opened on Aug. 18th, when all members were invited to attend a general meeting in the Palais d'Exercice, and then meet the committee of the section under which they were enrolled and obtain any information or tickets which they required. This palace, which is popularly known as the *Manége*, is well-fitted for the purpose to which it has been put, as the headquarters of business arrangement, for it is an enormous building in the centre of the city, easily accessible, near the University, and not a great distance from the *cliniques*. But the general trouble and turmoil of travel upset the fore-planned arrangements. Everyone was hot, dusty, and dirty, and in a short time the true uses of the preliminary meeting were lost sight of, the various alcoves which were designed to be the headquarters of different sections were completely deserted, while the centre of the building was used as a smoking promenade by everyone who was not struggling around the *poste-restante*, the restaurant, and the lavatory. The first two, it should be said, were admirably worked, but of the shameful inadequacy of the last a plain word must be spoken. One urinal and one water-closet were placed at the disposal of the whole Congress, and both were in the same little wooden hut, divided from each other by no partition. Moscow is according to European ideas very inadequately supplied with latrines, while the unblushing publicity of the East concerning the performance of all the offices of nature to a great extent prevails; but those responsible for the arrangements of the public meeting in the *Manége* ought to have remembered that the meeting was an international one, and not an oriental one.

The arrangements for the reception of ladies were much better, but there were, of course, by no means so many ladies to be provided for. They were well looked after by a competent local committee, who had taken all pains to make orderly provision for probable wants. From this little fact one lesson may be deduced, and that is that the numbers who attend these congresses are now so large that proper organisation for comfort is impossible. Thousands of persons surging into a foreign town cannot be made to feel at home, though hundreds possibly can. If the congresses could be confined to delegates the standard of comfort would be much higher, and the scientific character of the meetings would lose nothing by such a limitation. But as these congresses are at present constituted an enormous number of people have to be provided for, and temptation must be placed before them to pay their guinea and attend, for without a good sum of money in hand the meetings must result in a pecuniary loss, while there is no very clear reason why any State, or any individual, should meet that loss. But speculation on this point would lead us to speculation upon the uses of scientific congresses, a large subject not now under consideration.

On Thursday evening, Aug. 19th, there was a well-attended soirée in the Galleries of Commerce, all members of the Congress being invited to be present. The galleries are enormous new buildings constructed over vast arcades, with shops on either side, and form a prominent feature of modern Moscow, all the more prominent because their ornate, white façades in modern Italian style abut on the old red walls of the Kremlin. The programme of the evening included performances by Russian, Cossack, and Tzigane choirs, while refreshments were provided in the different galleries with truly Russian magnificence.

A generous offer has been made by a number of merchant princes in Moscow, who propose to endow an infirmary for epileptics and the weak-minded of both sexes to commemorate the Congress.

THE FIRST GENERAL MEETING.

Those who were fortunate enough to be present at the opening ceremony of the Congress witnessed an extremely brilliant sight. The organising committee, in selecting a suitable place for the three general assemblies, have been placed in a position of no little difficulty. To find a building capable of accommodating even a moiety of the 7000 members of the Congress, many of whom are accompanied by ladies, was an obvious impossibility. In ultimately selecting the Grand Theatre (*Bolshvi Tëatr*) the problem appears to have been solved in the best possible manner. This fine theatre, the largest in Europe, stands in the centre of a plain, just outside the *Kitai Gorod*, or "Chinese Town," a characteristic part of the city of Moscow, surrounded by walls which almost rival those of the Kremlin itself. The interior of the theatre was entirely renovated last year for the occasion of the gala spectacle at the time of the Coronation. On this occasion every seat appeared to be occupied some time before the opening of the Congress, which was fixed for 1 o'clock. As seen from the stage the sight was certainly a striking one. The prevailing dress appeared to be the ordinary evening dress of civilisation, but in all parts of the house this was relieved by more than a sprinkling of uniforms and decorations, and orders of all nationalities were worn by a goodly number of those present. The stage was occupied by the official representatives and delegates of the various nationalities, and here, as was to be expected, there was a brilliant array of official uniforms and decorations. Throughout the house, too, the summer toilettes of the ladies present, of whom there were many, added conspicuous touches of colour. Her Imperial Highness the Grand Duchess Elizabeth, the wife of the Grand Duke Sergé, occupied the stage box on the left side. Punctually at 1 o'clock the audience rose as the august patron of the Congress, the Grand Duke Sergé Alexandrovitch, took his seat at the centre of the table, which occupied the whole length of the front of the stage. To his Highness's right was the Minister of Public Instruction, his Excellency Count Delianof, and to his left Professor Sklifosovski, the President of the Organising Committee of the Congress. At the table were seated also the Mayors of Moscow and St. Petersburg and many of the representatives of foreign countries. The remainder of the stage was completely filled by foreign delegates and members of the national committees. The back of the stage was occupied by a full-length portrait of the Emperor, surrounded by numbers of tropical plants and trophies of flags of all nations.

The Grand Duke having declared the Congress officially open, Count Delianof rose and delivered a short address of welcome in the Latin tongue. He spoke of the lofty aims which had brought the members together and wished success

Digitized by Google

to their joint labours. Professor Sklifosovski, as president of the Organising Committee, who spoke in French, then gave a brief address. He welcomed the members of the Congress in the name of the oldest of the Russian universities. Russia, he continued, was no longer separated, as in the past, by a Chinese Wall from the rest of Europe. It had been the lot of Russia to protect the West from those fatal Asiatic influences which had for so long prevented her own development. He then passed on to discuss the question of languages. The multiplicity of languages had, he said, in the past been one of the great bars to international intercourse, and he proposed that an attempt should be made at the present Congress to come to some decision on the question of what language or languages should be employed at this and succeeding international gatherings. He suggested that each nation should elect two representatives, who should collectively form a committee to discuss this subject.

Professor Roth, the general secretary, then gave an account of the preliminary labours of the organising and executive committees. The present Congress was larger than any of its predecessors, the number of members exceeding 7300. Prince Galitzin, the Mayor of Moscow, then welcomed the members of the Congress in the name of the city of Moscow, and added that to commemorate the event the municipality had decided to offer a triennial prize for the best work on some selected medical subject, under conditions already described in THE LANCET. The speeches of the representatives of foreign countries then followed. The majority spoke in French, but the German and Austrian representatives spoke in German, the English in our own tongue, and the Czech and Bulgarian in Russian. The first and the most eloquent address was that of Professor von Koller, surgeon-general of the Prussian army, whose speech was received with loud applause. Space will scarcely permit of more than the mention of the many countries whose delegates addressed the house at more or less length. The representatives spoke in the following order: Germany, Austria, Czech, Hungary, England, Belgium, Denmark, France, Mexico, Italy, Japan, the United States, Spain, Norway, the Netherlands, Roumania, Portugal, Sweden, Turkey, and Switzerland. Professor Tarnovski, of the Russian Medical Council, and M. Dekhteref, representing the city of St. Petersburg, then spoke; the latter, in the course of his speech, cordially inviting the members of the Congress to visit St. Petersburg after their labours in Moscow were at an end.

Professor Roth then read the names of the representatives of foreign countries. The names, particularly the more familiar ones, were received with loud applause, which in many instances was not silenced until the owner of the name had risen and bowed his acknowledgments. Germany is represented by Professor Virchow, Professor Leyden, Professor Ziemssen, and Professor Waldeyer; Austria by Professor Gussenbauer, Professor Hlava, Professor Pertik, and Professor Riedeger; Belgium by Professor Crocq; Great Britain by Sir William MacCormac, Sir William Stokes, and Professor Simpson, of Edinburgh; the United States by Dr. Sayer, Dr. Senn, and Dr. Billings; Spain by Dr. Robert, of Barcelona; France by Professor Lannelongue, Professor Le Dentu, Professor Grassé, and Professor Pinard; Italy by Professor Dantona, Professor Bottini, and Professor Lombroso; and Switzerland by Professor Kocher and Dr. Roux.

After the addresses of the delegates, many of whom of necessity spoke with great brevity, there was an interval of five minutes. On the house re-assembling Professor Virchow at once ascended the rostrum on the left side of the stage to read his address on "The Continuity of Life as the Basis of Biological Science." His appearance was the signal for a loud outburst of applause, and it was some moments before the veteran professor could begin his speech. The subject of his address had been changed almost at the last moment, his original communication on "The Rôle of the Vessels in Inflammation" being reserved for one of the sectional meetings. The beginning of the address, which was delivered in German, was devoted to an interesting *résumé* of the various views of the nature of life which had been held at different times and by different observers, and of the successive discoveries which had widened man's knowledge of the nature and mechanism of vital action. Paracelsus had held that the life of a living organism was twofold; there was the life of the separate parts, the "*vita propria*"; and the life of the whole, or "*vita communis*." The speaker then passed in brief review the great discovery of Harvey of the circulation of the blood, the labours of Malpighi, the discoveries of Pasteur, and the great philosophical work of Darwin. All these had brought us nearer to the secret of what life is and what is its source, but it still remains a secret. Only two or three years remain to the opening of another century, and the orator concluded his address by expressing the hope that before the close of the twentieth century the problem of life might be solved.

The second address was that of Professor Lannelongue, of Paris, who received a scarcely less enthusiastic welcome from the audience than the preceding orator. The subject of his address was "The Surgical Treatment of Tuberculosis." Professor Lannelongue, who spoke in French, said that in former times local affections of all sorts, now known to be tuberculous in character, had been called by a number of different names. It was only by the recognition of the so-called tuberculous nodule that the common origin and character of all these different affections had been established. Later still the discovery by Koch of the tubercle bacillus had proved beyond a doubt, not only their identity, but also their infectious character. What was the duty of the surgeon in view of these conclusions? Obviously he must endeavour to remove the local centres of infection, which threatened the whole organism—to remove them as early as possible and as completely as circumstances would allow. The objections which had been raised to this method of reasoning do not bear criticism. It had been said that the tubercle bacilli are accompanied by other micro-organisms, the action of which will continue although the centres of tuberculous infection are removed. But the presence of other organisms is in the majority of cases the result of the open condition of the specific tuberculous centres, allowing access to the body of extraneous micro-organisms which would not otherwise obtain access to the tissues. In such cases there is doubtless a mixed infection. The method of surgical interference was in many such cases not available, particularly if it was uncertain where the original source of infection was situated. In these cases conservative methods must be followed; immobilising, extension, rest, and bloodless methods generally gave better results than operation. Sometimes good results could be obtained by the injection of microbicidal fluids into the tissues at the centre of infection. But the number of such cases was limited. In a majority of instances the watchword of the surgeon should be "*Agir tôt, agir vite*"—remove at the earliest opportunity the source of the infection—the tubercle bacillus.

Dr. Lauder Brunton, of London, who wore his Doctor's gown of scarlet cloth, then read an address on "The Relations between Physiology, Pharmacology, Pathology, and Practical Medicine," which will be found in another part of our present issue. Dr. Lauder Brunton spoke in French, and as the hour at which he rose was already a late one he greatly condensed his interesting address.

THE LATE MR. JOHN PHILLIPS, C.E.—Mr. John Phillips, who recently died at his residence, Disraeli-road, Putney, in his eighty-first year, had a considerable share in the introduction of the sewerage system which rescued London from the cesspool abominations and rendered it a healthy well-drained city. The evidence given by him before the Metropolitan Sanitary Commission in 1847 contains some woeful pictures of the filthy state of the basements in many localities due to overflowing of the cesspools. The egg-shaped sewer, now universally used, was invented by him—a question easily settled by reference to the Blue-books for 1847 (report of the Sanitary Commission)—and the first sewers of that section were laid down by him and the late Mr. John Roe, who was surveyor to the Holborn and Finsbury Commission. He was also the inventor of street gullies, and was among the first to make use of stoneware drain-pipes. During his active years Mr. Phillips held the appointment of chief surveyor to the Metropolitan Commissioners; he had, however, for many years lived in retirement, occupying himself with antiquarian studies relative largely to the past history of Putney and the connexion between it and the families of Oliver Cromwell and Thomas Cromwell, Earl of Essex. Papers on these subjects were published by him in the *Antiquarian* in 1880, and in the *Antiquarian Magazine* in 1882.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations, and having complied with the by-laws and regulations, have been admitted Members of the College, viz :—

Abbott, Horatio White, L.R.C.P. Lond.
Ackland, Charles Herbert, L.R.C.P. Lond.
Adams, Arthur Reginald, L.R.C.P. Lond.
Alcock, George Herbert, L.R.C.P. Lond.
Aldridge, Arthur William, L.R.C.P. Lond.
Alford, Herbert Thomas Marmaduke, L.R.C.P. Lond.
Allan, Herbert William, L.R.C.P. Lond.
Allan, Humphrey, L.R.C.P. Lond.
Anthony, Frederic, L.R.C.P. Lond.
Aslett, William Stacey, L.R.C.P. Lond.
Atkinson, George Louis, L.R.C.P. Lond.
Bahadurji, Jamshed Nassarvanji, L.R.C.P. Lond.
Baker, Alfred Eaton, L.R.C.P. Lond.
Barrett, Frederic Walter, L.R.C.P. Lond.
Barton, Eustace Robert, L.R.C.P. Lond.
Barton, John, L.R.C.P. Lond.
Batchelor, Ferdinand Stanley, L.R.C.P. Lond.
Battye, Walter Rothney, L.R.C.P. Lond.
Baylis, Henry, L.R.C.P. Lond.
Beckton, William, L.R.C.P. Lond.
Benham, Charles Henry, L.R.C.P. Lond.
Bennett, Henry Charles Plant, L.R.C.P. Lond.
Bennett, James, L.R.C.P. Lond.
Bergin, William Marmaduke, L.R.C.P. Lond.
Betteridge, Thomas, L.R.C.P. Lond.
Bonnin, James Atkinson, L.R.C.P. Lond.
Brett, Henry Clarence Marshall, L.R.C.P. Lond.
Brewer, Dunstan, L.R.C.P. Lond.
Brown, Robert Pollock, L.R.C.P. Lond.
Cade, Harry Mills, L.R.C.P. Lond.
Cardin, Herbert, L.R.C.P. Lond.
Chapman, Charles Leopold Granville, L.R.C.P. Lond.
Chapple, William Allan, M.B., Ch.B. New Zealand.
Charles, John Roger, L.R.C.P. Lond.
Cheesman, Herbert Hilton, L.R.C.P. Lond.
Churchill, Joseph Henry, L.R.C.P. Lond.
Cleveland, Arthur John, L.R.C.P. Lond.
Clifford, Harold, L.R.C.P. Lond.
Claud, Frank Henry Loveless, L.R.C.P. Lond.
Cobb, Ernest Herbert, L.R.C.P. Lond.
Coleman, Edward Hayling, L.R.C.P. Lond.
Collier, Robert Stanley, L.R.C.P. Lond.
Cotterill, Albert Ernest, L.R.C.P. Lond.
Deakin, Frank Newstead, L.R.C.P. Lond.
Dent, Howard Henry Congreve, L.R.C.P. Lond.
Dixon, Henry Cuthbert, L.R.C.P. Lond.
Dotson, Joseph Faulkener, L.R.C.P. Lond.
Downes, Godkin, L.R.C.P. Lond.
Dudgeon, Herbert William, L.R.C.P. Lond.
Duncan, George Ernest, L.R.C.P. Lond.
Dykes, Campbell, L.R.C.P. Lond.
East, William Norwood, L.R.C.P. Lond.
Ferguson, William, Alexander, L.R.C.P. Lond.
Fergusson, James Herbert, L.R.C.P. Lond.
Fox, Edward Hamilton Bruce, L.R.C.P. Lond.
Gaskell, Leonard Sandgrove, L.R.C.P. Lond.
Gervis, Charles Berkeley, L.R.C.P. Lond.
Gibbons, Charles James Preston Telford, L.R.C.P. Lond.
Godwin, Herbert James, L.R.C.P. Lond.
Greaves, Henry, L.R.C.P. Lond.
Haines, Aubrey Wheeler, L.R.C.P. Lond.
Hardwicke, George, L.R.C.P. Lond.
Harvey, Frederic, L.R.C.P. Lond.
Hitchins, Frederick Charles, L.R.C.P. Lond.
Hodgson, Cortis Rawsthorne, L.R.C.P. Lond.
Holmes, John, L.R.C.P. Lond.
Hughes, Sidney, L.R.C.P. Lond.
Hull, Alfred John, L.R.C.P. Lond.
Jackson, Wilfred Anthony Legh, L.R.C.P. Lond.
Jago, Thomas Dinnen, L.R.C.P. Lond.
Jamieson, Harold Henry, L.R.C.P. Lond.
Jeaffreson, Alfred Ernest, L.R.C.P. Lond.
Jones, Arthur Reginald, L.R.C.P. Lond.
Jones, John Llewelyn, L.R.C.P. Lond.
Kay, Richard, L.R.C.P. Lond.
King, Nevill Pearce, L.R.C.P. Lond.
Kirk, John Lamplugh, L.R.C.P. Lond.
Knechtel, Robert, L.R.C.P. Lond.
Lamb, Archibald Walter, L.R.C.P. Lond.
Lankester, Cecil Pryor, L.R.C.P. Lond.
Latham, Denyer William Fellows, L.R.C.P. Lond.
Lewis, Colton Taylor, L.R.C.P. Lond.
Lloyd, Lewis Jones, L.R.C.P. Lond.
Long, John Reginald, L.R.C.P. Lond.
Lord, Cyril Courtenay, L.R.C.P. Lond.
Lucas, Joseph John Scammell, L.R.C.P. Lond.
McClure, James, L.R.C.P. Lond.
Macdonald, John Norman, L.R.C.P. Lond.
Mackie, Frederic Percival, L.R.C.P. Lond.
McNally, George Johnston, L.R.C.P. Lond.
Mainprise, Cecil Wilmot, L.R.C.P. Lond.
Mannington, Frank, L.R.C.P. Lond.
Marles-Thomas, Theodore, L.R.C.P. Lond.
Martin, John, L.R.C.P. Lond.
Martin, Thomas, L.R.C.P. Lond.
Maver, Patrick Alpine James, L.R.C.P. Lond.
Maxwell, James Burns, L.R.C.P. Lond.
Maxwell, Richard Drummond, L.R.C.P. Lond.
Mayau, Marmaduke Stephens, L.R.C.P. Lond.
Meacock, Henry Charles, L.R.C.P. Lond.
Meade, Frank Elliott, L.R.C.P. Lond.
Meade, Norman Gerald, L.R.C.P. Lond.
Morgan, Walter Harmon, L.R.C.P. Lond.
Morland, Egbert Coleby, L.R.C.P. Lond.
Musselwhite, William, L.R.C.P. Lond.
Myers, Charles Samuel, L.R.C.P. Lond.
Newland, Henry Simpson, L.R.C.P. Lond.
Ogilvie, James, L.R.C.P. Lond.
Paterson, Archibald Richard, L.R.C.P. Lond.
Payne, Alfred Ernest, L.R.C.P. Lond.
Price, David, L.R.C.P. Lond.
Ransome, Gilbert Holland, L.R.C.P. Lond.
Roberts, David Faulkes, L.S.A. Lond.
Riley, Arthur, L.R.C.P. Lond.
Ryland, Robert Felix, L.R.C.P. Lond.
Sanderson, Edgar Stanley, L.R.C.P. Lond.
Sangster, John Ikin, L.R.C.P. Lond.
Sansome, Thomas, L.R.C.P. Lond.
Scott, Henry Harold, L.R.C.P. Lond.
Smith, Hugh Victor, L.R.C.P. Lond.
Snowden, Arthur de Winton, L.R.C.P. Lond.
Stephen, Lionel Henry York, L.R.C.P. Lond.

Wood, William Bird Herapath, L.R.C.P. Lond.
Woolley, Edward John, L.R.C.P. Lond.

FOREIGN UNIVERSITY INTELLIGENCE. — *Amiens (Medical School)*: Dr. Bax has been appointed Professor of Clinical Medicine.—*Barcelona*: Dr. Eusebio Oliver y Aznar, Professor in the Granada Medical School, has been appointed to the Chair of General Pathology.—*Berlin*: Dr. P. Silex has been promoted to an Extraordinary Professorship of Ophthalmology.—*Berne*: Dr. Max Stoos has been appointed Extraordinary Professor of Children's Diseases. — *Bonn*: Dr. B. Schörndorff has been recognised as *privat-docent* in Physiology. — *Breslau*: Dr. Kader, Assistant to the Professor of Surgery, has been recognised as *privat-docent* in that subject; Dr. Kühnau has been recognised as *privat-docent* in Internal Medicine; Dr. Henle has been recognised as *privat-docent* in Surgery. — *Chicago (College of Physicians and Surgeons)*: Dr. A. H. Burr has been appointed Assistant Professor of Medicine.—*Göttingen*: Professor Nicolaier has been appointed Principal Physician of the Medical Clinic.—*Freiburg (Baden)*: Dr. Bulius has been promoted to an Extraordinary Professorship of Gynæcology.—*Königsberg*: Dr. Bumm, Professor in Basle, has been offered the Chair of Midwifery and Gynæcology in succession to Dr. Dohrn.—*Lemberg*: Dr. Gregor Ziembicki and Dr. Victor Wehr have qualified as *privat-docenten* in Surgery.—*Rome*: Dr. Luigi Tarulli has been recognised as *privat-docent* in Physiology, Dr. Fillipo Rho as *privat-docent* in Medical Pathology, Dr. Raffaele Bastianelli as *privat docent* in Surgery, and Dr. Domenico Lo Monaco as *privat-docent* in Materia Medica and Pharmacology.—*Strasburg*: Dr. Karl Spiro, of Berlin, has qualified as *privat-docent* in Physiological Chemistry.—*Tübingen*: Dr. Albert Doderlein, Professor of Medicine in Gröningen, has been appointed Professor of Midwifery in succession to the late Dr. von Saxinger. — *St. Petersburg (Military Medical Academy)*: Dr. Georg Vlaieff and Dr. Nikolai Kulbin have been recognised as *privat-docenten* of Internal Medicine.—*Vienna*: Dr. R. Kretz has been recognised as *privat-docent* of Pathological Anatomy, and Dr. Lode as *privat-docent* in Hygiene.—*Würzburg*: Dr. Andreas Rosenberger has been appointed Extraordinary Professor of Forensic Medicine.

THE CHEMISTS' EXHIBITION.—This annual exhibition grows in importance and this year has arrived at the dignity of an international exhibition as certified under the provisions of the Board of Trade. Pharmacy affords an excellent opportunity for making a bright and attractive show and the preparation and compounding of drugs is a rapidly developing branch of home industries, and it is not surprising to learn that next year, consequent upon the excessive demands upon space, the exhibition will be held in the Agricultural Hall. Some may have been led to exclaim, "To what base uses, &c.," but the exhibition recently held in Covent Garden Theatre was well and tastefully arranged and the scene viewed from the upper tiers was quite Oriental while the perfumes in the air added reality to the picture. It is evident that the Chemists' Exhibition has become very popular all the leading chemists, druggists, and perfumers, now taking an active and interested part in it. We congratulate the organisers, the proprietors of the *British and Colonial Druggist*, on having initiated a successful movement

Digitized by Google

THE annual meeting of the Nottingham Medico-Chirurgical Society was held on July 21st, Dr. W. B. Ransom, president, being in the chair. The annual reports of the secretaries, treasurer, and librarian were severally read and adopted. The following were elected as officers for the ensuing year:—President: C. H. Cattle. Vice-Presidents: W. B. Ransom and E. Snell. Council: J. H. Cox, G. B Wray, A. E. Nuttall, F. Rothera, and C. Macmillan. Secretaries: W. E. Tresidder and E. C. Kingdon. Librarian: W. J. Stephens. Treasurer: T. Geraty. Library Committee: A. W. C. Peskitt, F. J. Lander, J. S. Bolton, and J. Mackie. Pathological Committee: Miss Gray, E. J. O'Mallane, and A. Waring. Finally, on the motion of Mr. Tresidder, seconded by Dr. Cattle, it was resolved that the best thanks of the society be accorded to the retiring president, Dr. W. B. Ransom.

FREEDOM OF THE CITY OF MANCHESTER.—At a special meeting of the City Council on the 18th inst. it was unanimously resolved to present the freedom of the city to Dr. A. W. Ward, the Principal of Owens College, who is shortly about to retire from that position, and also to Mr. Herbert Philips, a much respected member of a family honourably connected with Manchester for more than a century. The College will lose in Dr. Ward a man who has well represented the dignity of culture and done much to uphold and extend the influence of the College. Mr. Herbert Philips has for many years taken a prominent part in philanthropic work, and has particularly interested himself in schemes for the physical recreation of the people. He has long been a valued member and vice-president of the Sanitary Association, and is also vice-president of the Smoke Abatement League.

DONATIONS TO ABERDEEN HOSPITALS, &c.—The Thurburn Cooking Depôt, Aberdeen, having been discontinued, and the trust being wound up, the trustees have allocated the funds as follows:—Aberdeen Royal Infirmary, £1200; Aberdeen Hospital for Incurables, £1200; Aberdeen Hospital for Sick Children, £1000; Aberdeen Asylum for the Blind, Aberdeen Dispensary, and the Association for Improving the Condition of the Poor, £750 each; Aberdeen District Nursing Association, £500; Aberdeen Soup Kitchen and the Ophthalmic Institution and Hospital, £250 each; Aberdeen Free Breakfast Mission, Female School of Industry, and Seabank Home for Fallen Women, £150 each. Total, £7100; any available balance to go to the Royal Infirmary. The result of the Hospital Saturday Demonstration will be the distribution of £750 among the Aberdeen hospitals. The Special Jubilee Fund for the hospitals amounts to £5300.

THE UNITED KINGDOM POLICE SURGEONS' ASSOCIATION.—The annual meeting of this association was held at Exeter Hall on July 28th, when the report of the council was received and adopted and copies were ordered to be sent to all police surgeons whose addresses are known. A resolution congratulating the retiring President, Sir H. D. Littlejohn, on his being appointed Professor of Forensic Medicine in the University of Edinburgh was unanimously adopted, and Mr. E. K. Houchin, metropolitan police surgeon and deputy coroner for East London, was chosen as his successor. A form for taking notes of post-mortem examinations, which had been issued under the sanction of Dr. Danford Thomas, the coroner for Central Middlesex, was considered and adopted, and it was resolved that a copy should be sent to each member of the association. A letter was read from Dr. Craig, of Birmingham, urging that coroners should be communicated with, suggesting on the part of the association that police surgeons should be called in to make necropsies and give evidence in cases where no medical man had been in attendance during life, and it was resolved that this should be done.—The following officers and council were elected for 1897-98:—President: E. K. Houchin, L.R.C.P. Edin. Vice-Presidents: T. Holmes, F.R.C.S. Eng., T. Bond, F.R.C.S. Eng., Sir H. Littlejohn, M.D. Edin., and H. Barnes, M.D. Edin. Treasurer: H. Nelson Hardy, F.R.C.S. Edin. Hon. Secs.: F. W. Lowndes, M.R.C.S. Eng., and H. C. Hopkins, M.R.C.S. Eng. Council: J. R. Baumgartner, M.R.C.S. Eng., J. F. Craig, M.D. Aberd., C. Eastwick-Field, M.R.C.S. Eng., G. H. Heald, M.R.C.S. Eng., W. J. Heslop, F.R.C.S. Edin., D. McDonnell, M.D. Irel., L. Maybury, M.D. Irel., H. W. Roberts, M.R.C.S. Eng., W. Roocroft, M.R.C.S. Eng., C. Templeman, M.D. Edin., W. Washbourn, L.R.C.P. Lond., and S. Wyborn, M.R.C.S. Eng.

PRESENTATIONS TO MEDICAL MEN.—To mark their appreciation of the services rendered by Mr. J. Dickinson Leigh, M.B., C.M. Edin., &c., as honorary instructor to the St. John Ambulance Classes formed in connexion with the Lumpsey and Huntcliff mines, the members presented him with a case of silver-mounted dessert knives and forks at a meeting held at Brotton-in-Cleveland, Yorkshire, on Aug. 9th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Zd. Nieszkowsk, editor of *Medyzyna*, a Warsaw medical journal of considerable repute amongst Polish medical men.—Dr. Don Cesareo Magdalena, a Madrid bacteriologist.—Dr. Ask, Professor of Surgery in the University of Lund.—Dr. Finotti, *privat-docent* of Surgery in Gratz.—Dr. Sousa Martins, of Lisbon, a well-known authority on hygiene and the representative of Portugal at the Vienna Conference. It was due to his initiative that severe measures were undertaken in Portugal against the spread of cholera and yellow fever.

THE NEXT LORD MAYOR OF MANCHESTER.—In accordance with a requisition signed by every member of the council Mr. Alderman Gibson, chairman of the Gas Committee, has consented to become the next Lord Mayor of Manchester. When thirteen years of age he was apprenticed to Mr. Pittinger, a medical practitioner, of Sutton-on-Trent. This gentleman it seems had a druggist's shop in Newark, in which much of Mr. Gibson's time was spent. He did not proceed farther in his medical career, but in course of time began on his own account as a druggist in Manchester. He subsequently established himself as a medicated lozenge manufacturer, and the business has become both extensive and very prosperous. As may be remembered, a recent deputation to him as chairman of the Gas Committee with respect to the use of water gas did not meet a very encouraging reception.

LAUNCESTON GENERAL HOSPITAL, TASMANIA.—The report of the General Hospital, Launceston, Tasmania, for the year 1896 shows that 70 patients were under treatment on Jan. 1st; 780 were admitted during the twelve months, 693 were discharged, 83 died, and 74 remained on Dec. 31st. The daily average number of in-patients was 76, and the average stay in hospital was between thirty-five and thirty-six days. There were also 1178 out-patients treated, among whom there were 8 deaths. The present building was erected as a hospital and has been established thirty-two years. It is a general hospital, with the exception that lying-in cases are not admitted. There are 122 beds. The town and district have a population of about 50,000. The cost of construction was defrayed by the Government, and the whole of the annual maintenance is contributed by the Government, except what is received from patients who pay fees. The gross expenditure for 1896 was £5762, and the patients' payments were £632. The resident medical staff consists of a surgeon-superintendent (Mr. F. J. Drake, M.A., M.B., B S Melb.), and a house-surgeon. Two students have attended the medical practice and two students the dental practice. There are four members of the honorary consulting staff and two dental surgeons. The course of instruction for nurses consists of lectures on General Anatomy and Physiology, on Minor Surgery, and on Nursing, the latter section comprising lectures on "Hospital Etiquette," and on the "Distinction between the Work of Doctor and Nurse." The hospital statistics are of the usual character. They include 29 cases of phthisis, 21 of general paralysis of the insane, 30 of pneumonia, 31 of cancer, and 65 of enteric fever, of which latter only one case was admitted from the end of June to the end of November.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ARKLE, G. M., L.S.A. Lond., has been appointed Medical Officer, West Derby Union; North part of No. 2 District.

BEADLES, H. S., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Grimsby and District Hospital.

Digitized by Google

BENNETTS, A. J., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Assistant House Surgeon to the Royal Albert Hospital, Devonport.

BROWNING, B., L.R.C.P., Lond., M.R.C.S. Eng., D.P.H., has been re-appointed Medical Officer of Health to the Weymouth Urban District Council.

CARRUTHERS, E. J. W., M.D. Edin., has been appointed Medical Officer of the Congleton District of the Congleton Union.

CLAY, JOHN, M.B., B.S. Durh., has been appointed to the post of Surgical Registrar in the Royal Infirmary, Newcastle-on-Tyne.

DINGWALL, A., M.B., M.S. Univ. Aberd., has been appointed Medical Officer of the Pembridge District.

FERNIE, J. F., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Staffordshire General Infirmary.

FRY, W. W. B., M.B., M.S. Edin., has been appointed Medical Officer of Health to the Builth Urban District Council.

GOWING, B., M.R.C.S. Eng., L.S.A. Lond., has been appointed Medical Officer, No. 5 District, Wortley Union.

GROSS, C. F., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer of Health to the East Ashford Union, No. 7 District.

KENDALL, H. W. M., M.R.C.S. Eng., L.S.A. Lond., has been appointed House Surgeon to the Central London Ophthalmic Hospital

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

DUPLICATE PERIODICALS.

THE Dundee Medical Library has on hand a number of duplicate volumes of the *Edinburgh Medical Journal, Medical Times and Gazette, Journal of Mental Science*, &c., which the committee is desirous of giving in exchange. Full particulars can be obtained on application to the Assistant Librarian, Medical Library, University College, Dundee.

Arytenoid.—We see no objection provided that the source of the degree be added after the letters signifying the same.

M.A.D. (Lowestoft).—We never prescribe in any way. Our correspondent must consult her own medical man.

AN OBJECTIONABLE ADVERTISEMENT.

IN our issue of Aug. 14th an advertisement was inserted which commenced "£25 down and £25 in a month." The advertisement was sent to our office accompanied by a covering letter in which the advertiser was described as "Dr. Young." It is obviously impossible to check the genuineness of every advertiser, although our clerks use every care. They can only take a person's description of himself as correct unless it is proved to be otherwise. We are sorry to find that "Dr. Young" is an irregular practitioner whose style and methods of practice may be judged from the following circular issued in his name:—

Read this Attentively.

When suffering from a disease or illness which others cannot cure,

CONSULT WITHOUT DELAY

the far famed and well tried experience of

MR. J. J. YOUNG

UNREGISTERED

CONSULTING PHYSICIAN AND SURGEON,

HIGH STREET, MIDSOMER NORTON,

SOMERSET,

PERSONALLY OR BY LETTER.

Who was legally apprenticed for 5 years in Ipswich, Suffolk, to one of the leading practitioners of the town, in the year 1840. Mr. Young also graduated at Oxford University, and duly walked the London Hospitals and passed through every ordeal of the profession with classical honours. Professor of the principles and practice of physic, the symptoms, causes and treatment of all diseases, from the period of birth to an advanced age, from a practical experience of upwards of 50 years.

For 25 years Mr. Young acted as general medical assistant, having had at intervals entire charge of some of the largest and best practices in England, Scotland and Wales.

The following are a few of the diseases which have claimed for him a reputation for the cure of which, as yet, he has had no rival:—

The Eye. The Ear. Gout. Rheumatism, Sciatica, Neuralgia, Wounds. Ulcers, Bad Legs, Sores, Skin Diseases, Lung and Chest Diseases, Cancerous affections of all kinds and all irregularities in respect to males and females from whatever cause,

which have baffled the skill and puzzled others of the profession.

Mr. Young has for years past associated with men of eminence in the consulting ranks of the profession, whose work makes the last part of the 19th century memorable in the history of medicine & Queen Victoria, and has prescribed for Princes, Lords, Dukes, and Noblemen. N.B.—but boasts proudly of the supreme honour and national pride of being indebted to the working classes, from which circle sprang his matchless and unlimited fame. Mr. Young was for upwards of 20 years in practice in Ipswich, Suffolk, where he left an undying fame for practical skill, recognised alike by the public and the profession at large.

HOURS OF ATTENDANCE—10 A.M. to 9 P.M.

CHARGES—In all cases will be most moderate and within the reach of all.

ADVICE GRATIS.

E. P. B. (Southampton).—The results of such an investigation would be most valuable. It would, however, require an enormous amount of work—house-to-house visiting and bacteriological examinations. We think that probably the best person to undertake such a task would be a "research scholar."

AN URGENT APPEAL.

To the Editors of THE LANCET.

SIRS,—May I crave a small space in THE LANCET for an appeal to the more successful members of our profession on behalf of the widow and eight children of the late Mr. Campe, a medical man practising in this neighbourhood, who died quite suddenly on Sunday last. The post-mortem examination showed extensive heart disease, which so sadly crippled his untiring efforts to support his wife and large family. They are, I regret to say, left absolutely unprovided for, and I earnestly entreat all who can to forward me a subscription, however small, which I will gratefully acknowledge (through your courtesy) in THE LANCET; especially do I desire to enlist the generous sympathy of members of his own school (Guy's).

I am, Sirs, yours faithfully,

WM. ASTLEY COOPER.

36, New-road, Rotherhithe, S.E., Aug. 25th, 1897.

HOSPITAL REFORM ASSOCIATION.

MR. T. GARRETT HORDER, the hon. secretary, has received a donation of ten guineas from Mr. William Allingham, F.R.C.S. Eng., towards the funds of the Association.

A. B.—The query of our correspondent is dealt with in Part XI. of the Lunacy Act, 1890. Section 315 (1) is as follows: "Every person who, except under the provisions of this Act, receives or detains a lunatic, or alleged lunatic, in an institution for lunatics, or for payment takes charge of, receives to board or lodge, or detains a lunatic or alleged lunatic in an unlicensed house, shall be guilty of a misdemeanour, and in the latter case shall also be liable to a penalty not exceeding fifty pounds." Apart from the question of legality we think that the circumstances of the case which our correspondent puts are such as cannot fail to be detrimental both to the individual referred to and to the other inmates. They are also highly prejudicial to the best interest of the cause which the institution professes to serve.

Cymric would be greatly obliged for any information as to the best books or tuition in London for the purpose of acquiring an elementary knowledge of the Welsh language.

Mr. C. E. Murphy.—The paragraph is certainly in execrable taste, but we are quite certain that the medical man alluded to objects more than anyone else to its insertion.

F. D. B.—We should say the fairest arrangement would be to divide the fee.

Dr. L. Kidd.—We do not consider the matter worth further notice.

"A QUERY IN OPHTHALMIC SURGERY."

To the Editors of THE LANCET.

SIRS,—I have waited for a more prominent ophthalmic surgeon than I am to answer the "Query in Ophthalmic Surgery" in THE LANCET of Aug. 7th. But as no answer has as yet appeared I, believing "X. Y. Z." to be anxious to hear the opinion of someone experienced in eye surgery, venture to give my advice for what it is worth. The question, Shall a cataract be removed from one eye while the sight of the other eye is perfect? has often been discussed. Though knowing that many medical men are inclined to give an answer in the negative, I would advise an operation in the case mentioned, because: (1) a cataract will make the condition of the afflicted eyeball the more amblyopic the longer it is allowed to remain; (2) should the as yet unaffected eye become similarly diseased the chances of success of operating may be less favourable than they are at present; (3) the cataract in the case mentioned is most probably of a soft, milky nature—cataracta Morgagniana—the removal of which by lance cut or needle discission (absorption) is a comparatively trifling operation; (4) even if the operation should be unsuccessful in restoring sight (amaurosis could be diagnosed previously to operation) the cosmetic advantage should be considered,—the patient being a young female; and (5) with the present "technique" in removing cataracts no anxiety in regard to a failure of the operation as such need be entertained. Should "X. Y. Z." remain still doubtful what to do he may leave the decision to the girl herself.

I am, Sirs, yours faithfully,

Grosvenor-street, W., Aug. 23rd, 1897. B. SCHWARZBACH, M.D.

Mr. Ed. E. Mayer.—The Royal College of Surgeons of England admit to the second, third, and final examinations candidates holding foreign diplomas, which entitle the holder to practise in the country where he obtained the diploma and which have been granted after education and examination equivalent to those required by the College. He would ascertain whether the College would so consider his degrees by specific inquiry of the Secretary of the College. There is a regular course of instruction at the National Hospital for the Paralysed and Epileptic, Queen-square. Particulars can be obtained by applying to the Secretary.

Mr. T. F. McDonnell.—The Infectious Diseases (Notification) Act only provides a fee of 1*s.* when a case is notified by a medical man which "occurs in his practice as medical officer of any public body." It is held that a Poor-law medical officer serving a board of guardians comes within that provision, and that he is only entitled to a fee of 1*s.*

L.S.A. Lond., L.M. Dub.—Judging by the statement before us B was right in going the first time, as it may have been a case of urgency. He should, however, have given up the case entirely to A, if, indeed, A chose to go on with it, and not have offered to see it "in conjunction" with A.

Mr. S. Gross.—Text-book of Chemical Physiology and Pathology, by W. D. Halliburton, M.D., B.Sc. Lond. (London: Longmans, Green, and Co.)

Mr. M. D. Rogers.—We regret that we are unable to assist our correspondent.

THE MANCHESTER MEDICAL GUILD.

WE have received the following letter, with a request for its publication, from the Secretary of the Manchester Medical Guild:—

[COPY.]

"Manchester, July 15th, 1897.

"DEAR SIR,—It has been reported to the Council of the Medical Guild that you have permitted yourself to become the instrument of a Medical Aid Association, which is promoting it objects against the unanimous opinion of the medical practitioners of the district, and I am requested to point out to you that such action on your part (without considering it as it affects your medical brethren) will, if persisted in, have a most baneful influence on your own future career. These associations are held in such evil repute by the profession that the medical journals will not knowingly insert their advertisements when they are in need of medical officers.

"No man can set at nought the opinion of his profession without injuring his own usefulness, and I venture to express the hope that you will see your way to retire from a position into which you may have been led unwittingly. Any doctor can make a living amongst a working-class population by conducting his practice in the time-honoured manner. I am assured he can do so from the very start, and every year his position becomes more secure; but it is not so with men who become the servants of organised laymen.

"Yours truly,

"ALEXANDER STEWART, Hon. Sec. the Medical Guild."

"THE CLIMATE OF CORSICA."

To the Editors of THE LANCET.

SIRS,—At page 235 of THE LANCET of July 24th I notice a query by "O. H." regarding the climate of Corsica, and have seen no reply given. If he will consult Section 7:6 of the *Medical Digest* he will be able to obtain all the information he requires, as therein are several references to the literature of this subject. I am, Sirs, obediently yours,

RICHARD NEALE, M.D. Lond.

Boundary-road, South Hampstead, Aug. 25th, 1897.

Professional Reader has omitted to enclose his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. ABSTRACT OF THE

President's Address

ON

CANADA IN ITS MEDICAL ASPECTS.

Delivered at the Sixty-fifth Annual Meeting of the British Medical Association at Montreal, August–September, 1897,

BY T. G. RODDICK, M.D.,

PROFESSOR OF SURGERY IN MCGILL UNIVERSITY, MONTREAL.

GENTLEMEN,—I rise to welcome you on behalf of the medical profession in Canada, and to thank you for the honour conferred on this city and country by your presence here to-day. Would that I could find suitable language in which to thank you also for the high honour you have done me in electing me to preside at this great meeting of the British Medical Association—an honour which is appreciated none the less by the consciousness that it is not a personal matter, but a compliment to Canadian medicine.

This meeting of the British Medical Association in Canada is an event which will serve still more to impress upon the memory of our people the year 1897, the year of the Diamond Jubilee of our beloved Sovereign, Queen Victoria. In no part of her vast empire—not even its very heart—did her subjects celebrate the great event with more enthusiastic loyalty and devotion than in Canada, especially in this province, the home of the French Canadians. We Canadians of both tongues love and honour our Queen. Long may she live. Deeply, too, have we appreciated here the splendid reception accorded in the old home to our Premier, the Right Hon. Sir Wilfrid Laurier, whose distinguished bearing and grace of manner eminently fitted him for the important part it was his peculiar privilege to play in the magnificent ceremonies of the Jubilee. A French Canadian, Sir Wilfrid Laurier's presence in England as the chosen representative of the Dominion was an object lesson to the empire and to the world in the harmony existing between the two nationalities which comprise the Canadian people. And here let me express, on behalf of every representative from the British Isles, and on behalf of every Canadian present, the genuine pleasure we feel in having among us on this memorable occasion so many of our brethren from the United States. This only proves the cosmopolitan character of our profession; this is only another recognition of the unity of medicine. Legislators may squabble, the air may be filled with wild alarms, and war may appear imminent day by day, but our relations are not disturbed in the slightest degree; our interests are common—we are kinsmen in science; we go forward hand in hand, irrespective of race or creed or colour, having one intent only—the advancement of our noble profession, and through that the amelioration of the ills of mankind. It is my privilege also to welcome the representative of another Republic, La Belle France, to whose gifted men of science our profession is so greatly indebted. This gentleman, who bears the credentials of his Government and officially represents the great nation of which he is so bright an ornament, is known far and wide as the Professor of Physiology in the University of France, Dr. Charles Richet. In coming to Canada it cannot be said, nor will he feel, that he comes to a foreign country, for in the Province of Quebec he will find another France, with a delightful mingling of the old and the new—his own beautiful language spoken with all the grace and purity of the old *régime*. But we are further honoured by the presence among us to-day of the most illustrious surgeon of our generation, Lord Lister, who stands for the rise and zenith of modern surgery. It has been well and truly said that as long as surgery is scientifically discussed Lord Lister's name cannot fail to be mentioned. We have only to compare the surgery of the time before 1873 with the surgery as practised to-day to appreciate all that he has done for the science. The remark is frequently heard that Lord Lister has made operative proceedings possible which only twenty-five years ago would have been considered criminal. Undoubtedly, the most powerful agency in the development of surgery in this century has been the introduction of the antiseptic and aseptic methods of wound treatment which he initiated. It is due to his efforts that surgical wards have been freed from pyæmia, and the mortality of lying-in hospitals reduced to the limits of normal parturition. For the past twenty years honours many and great have been showered upon him. Oxford, Cambridge, Edinburgh, Glasgow, Dublin, Toronto, and now McGill have vied with one another in hastening to do him homage. Our Sovereign, in conferring upon him the richly deserved distinctions which he bears with such gracious dignity, only gives expression to the general feeling of his countrymen throughout the empire and his admirers the world over. We are glad, I say, to have him with us to-day; his presence is an intellectual stimulus and an energising force in our deliberations.

It is, I understand, an unwritten law of the Association that the President shall not in his address encroach upon the topics which belong by right and usage to the readers of the main addresses and to the presidents of the various sections. I have observed that the majority of my predecessors have contented themselves with discoursing on objects and circumstances of local interest; they describe the town or city in which the meeting is held, or perhaps they discuss questions of a public character. In the absence of an address on Public Medicine others have taken that for their theme. It has been my unhappy lot to select and consider subjects only to find in quick succession that they had already been appropriated, either by the Association *Journal*, in describing so fully Montreal and its surroundings, or by the editors of the official guide or souvenir, who have given a very comprehensive description of Canada, or by some of the gentlemen who preside over the sections, who, I have been led to understand, purpose discussing questions of medical education. I fear, therefore, that what I have to say this afternoon will fall far short of the brilliant presidential addresses which members of this Association have been accustomed to in other years. Indeed, when I look at the long roll of eminent men who have been my predecessors in this high office—men oftentimes distinguished for their literary gifts as well as for their exalted position in the medical world—I confess that I marvel at my temerity in accepting so great a responsibility. In speaking of my predecessors allow me especially to refer to the retiring President, Dr. Henry Barnes, whose courteous and kindly manners, together with his sterling ability, make us all glad to know that his election as a Vice-President for life ensures his continued official and active connexion with the Association. Here might I also be permitted to say how greatly I appreciated the many kindnesses and courtesies extended to me by the President (Dr. Saundby) and members of the Council when in London last winter making the initial arrangements for this meeting. With respect to the other addresses which it is customary to deliver on these occasions, medicine will be dealt with by one whose reputation is now world-wide—by our Osler—whose professional education was in great part received in this city, and who, I am happy to say, is still a Canadian. How he has been able to escape the alien law is a puzzle to many; but he has really only been borrowed for a time; he is merely passing through the United States in bond. We are only waiting until we can find a place large enough to hold him, when we shall coax him back. Sorry am I that his old colleagues in his own department of medicine—Howard and Roes and Macdonnell—are not here to share with us the genuine pleasure we experience in finding him in the position which he occupies to-day. You will hear addresses in Surgery and Public Medicine delivered by gentlemen who have devoted their lives to their special subjects. Before proceeding, however, with the remnants of subjects which my *confrères* have been graciously pleased to leave for my share on this occasion, allow me first, for the benefit of those who may not be acquainted with the work of the British Medical Association, to give in as few words as possible a general idea of its organisation.

[Dr. Roddick then gave an account of the foundation and objects of the British Medical Association and continued:]

The Canadian people, and especially the citizens of Montreal, are highly gratified that Canada should be the first country without the United Kingdom to be honoured by a meeting of the British Medical Association; and while they hope that it will not be long before the honour is repeated, our people are not insensible to the claims of other portions of the empire, more especially the great island continent of the Antipodes, Australia. Either Sydney or Melbourne would be a fit meeting place for such an imperial organisation as this; and should the next meeting which is held outside the British Isles be held under the Southern

Digitized by Google

Cross our hospitable Australian kinsmen may count on a large contingent from the Dominion of Canada.

CLIMATIC CONDITIONS OF CANADA.

As it may be presumed that to the majority of those present here to-day Canada is almost an unknown country, I have thought that among one or two other subjects a few remarks on the atmospheric conditions and health resorts of the Dominion would not be without interest. The best way to understand the atmospheric conditions of a country is first to understand its physical features. The physical features of Canada are very remarkable. Broadly speaking, the country is separable by climatic and physical conditions into three great regions—the Eastern, Central, and Western Regions—which approximately run north and south in the general trend of the continent. The eastern region, which includes the older provinces of the Dominion—Ontario, Quebec, Nova Scotia, New Brunswick, and Prince Edward Island, besides the great fur territory stretching far to the east and north-east of James's Bay—extends from the Atlantic to Lake Superior and the chain of Great Lakes running in a northerly direction from Lake Superior to the Arctic Ocean. Between this great chain of lakes and the eastern base of the Rocky Mountains is the immense interior continental plain which constitutes the central region of Canada, its southern part consisting of open prairie, its northern part of forest lands. The third part of the division, the western region, is naturally very well defined, consisting of the wide and wild mountainous border of the continent on the Pacific side—the Rocky Selkirk and Gold Ranges, which form the great Cordilleran belt, whose average width in Canada is 400 miles. Eastern Canada, our first and largest region, is geologically of very ancient origin. Here geologists have placed the nucleus of the continent—the broad belt of crystalline rock of great antiquity called the Laurentian Plateau. This region is remarkable for its immense number of lakes, large and small, and for its irregular and winding rivers with numerous rapids and falls. Between the Laurentian Plateau on the north and the Appalachian mountain system on the south lies the great valley of the River St. Lawrence. The basin of this majestic river covers 530,000 square miles, of which 460,000 are in Canada. Above the city of Quebec the base of the Laurentian highlands and the ridges of the Appalachian system diverge, and the mighty river flows through an extensive low country of notable fertility, in earlier days the great granary of Canada. It may be added *en passant* that Mount Royal, which gives such distinction and character to our city, represents the basal remnants of a volcanic vent of great antiquity. From its picturesque summit may be seen similar abrupt elevations far off towards the east and south—Montarville, Belœil, or St. Hilaire, Mount Rougemont, with Mount Yamaska behind it, Mount Shefford, and the conical Mount Johnson or Monnoir. The Adirondacks are visible in the distance to the south-west, and the Green Mountains to the south-east.

Included in the Eastern Region is one of the most remarkable geographical features of Canada—the great fresh water lakes or inland seas, Superior, Huron, Erie, and Ontario, which form the perennial reservoirs of the St. Lawrence. Together with Lake Michigan, which is wholly in the United States, they have an aggregate area of 94,750 square miles, an area larger than that of Great Britain. They stand at four distinct levels above the sea—Ontario 247 feet, Erie 573 feet, Huron 581 feet, and Superior 602 feet. The Niagara Falls, the greatest and most impressive of the natural wonders of our continent, are the direct result of the great height of Lake Erie above Lake Ontario, the river connecting the lakes being only a few miles long. Besides the St. Lawrence, Eastern Canada has several other great rivers, notably the Ottawa, which has a course of 1800 miles and a basin of nearly 1,000,000 square miles, the St. Maurice, the Saguenay, and the St. John, the glory of New Brunswick, which, together with the Atlantic Slope, has a basin of 50,214 square miles. The Central and Western Regions also have their abundant share of large and small lakes and great rivers, an account of which would fill reams of paper. It should be noted that the Canadian rivers and lakes collectively cover an area of 130,000 square miles, and contain one-half the fresh water on the globe. I draw special attention to this series of vast lakes and rivers because it exerts an immense and beneficent influence on the climate of Canada. It preserves the mean temperature, while the land experiences the extremes. In summer the water is cooler and in winter warmer than the land conditions, which tend to modify the differences and to favour uniformity of climate. Without these waters, too, we should have vast regions of comparatively little value, as in Africa, Asia, and in the United States west of the Mississippi river, where large tracts of land far from water are nothing more than arid wastes. Our climate is more uniform than that of Europe; the meteorological differences are produced by position alone, but Europe has a higher mean temperature, and the extremes there are not so marked or so wide apart as in Canada. Owing to the great area of Canada, extending over 20° of latitude, or from the latitude of Constantinople to that of North Cape in Norway, the range of temperature is naturally very wide. The southern boundary stretches over fully 4000 miles, along which line we find that Southern Ontario has the latitude of Central Italy, Nova Scotia that of Northern Italy, Manitoba and Vancouver that of Central Germany. Speaking generally, the Canadian summer may be stated at from 60° to 70° F. From its vast and varied extent Canada may be said to be the possessor of several climates. Taking Solly's classification as to position, we have in Canada all the three land climates—the low, the medium, and the high. The first has an elevation up to 2500 ft., the second up to 4500, and the third from 4500 upwards. As to temperature and humidity, Canada comes under the category of "cold, moderate, and dry."

HEALTH RESORTS.

In the eastern region of the Dominion there are at least two localities which have been proved to possess many of the qualities which constitute a climate for convalescents from fevers and other depressing diseases, and also for phthisis in the incipient stage. I refer to the region in the Province of Quebec among the Laurentians north of this city, of which the village of Ste. Agathe is the centre, the other being the Muskoka District, in Ontario. The first has been called the Adirondacks of Canada, having many of the features, physical and climatic, of that now celebrated plateau situated in the north-eastern part of New York State, and stretching from the Mohawk Valley in the south 150 miles north, almost to the frontier line. The average elevation of the two regions is about the same, being from 1600 to 1800 feet. The immense pine forests, together with the moderate temperature, constitute the chief characteristics of the Canadian district from the medical point of view. No very systematic meteorological observations have yet been taken of the Ste. Agathe region, but the indications will probably prove to be very similar to those of the American resort. It is in contemplation to erect a sanatorium on Trembling Mountain, overlooking the village of Ste. Agathe, which will doubtless in time rival the Adirondack Cottage Sanatorium near Saranac Lake Village, which has proved such a marked success under the able management of Dr. E. L. Trudeau. The elevation of the sanatorium will be 2500 feet, thus having an altitude of nearly 900 feet greater than the establishment at Saranac. It is the intention of the Quebec Government to set apart a sufficient portion of the Crown lands to form a natural park in that part of the province. It will be called the Trembling Mountain Park, and will cover an area of 100,000 acres of land, in which are several beautiful lakes. Within the boundaries of this park the sanatorium will be constructed. There is therefore no reason to doubt that we will shortly have within our own lines a health resort possessing all the advantages of the Adirondacks region, and capable of affecting for good the same class of patients now so decidedly benefited by a residence in those mountains.

One hundred miles north of Toronto, in the highlands of Ontario, is the Muskoka Lake region, an area of about 10,000 square miles, perhaps the most picturesque portion of the whole province. Within this district, which has a mean altitude above the sea of about 800 ft. (200 ft. above Lake Huron), there are nearly a thousand lakes and ponds, connected by innumerable streams. The chief lakes are Muskoka, Rosseau, and Joseph. These contain about 400 islands. It is a region abounding in pine forests; the climate is dry, and the air pure and invigorating. The Muskoka region has been found undoubtedly to possess remarkable climatic advantages for those with phthisical tendencies. The death-rate from phthisis in this section of Ontario is proved to be less than one-tenth the rate which obtains in other parts of the province. At Gravenhurst the Muskoka Cottage Sanatorium for the cure of incipient phthisis has recently been founded, under the best auspices,

Digitized by Google

with accommodation for forty patients. The present sanatorium consists of a large and well-planned main building, surrounded within easy distance by a number of small cottages. The grounds, which embrace seventy-five acres, are situated on Lake Muskoka. Pine forests and rocky ridges protect the buildings on the north and west sides, whence come the colder winds in winter. Like the Adirondacks Sanatorium, the intention is to occupy it all the year round. The progress of this institution, at present in the experimental stage, will be watched with much interest.

In the central region of Canada, that section of the north-west territories known as Southern Alberta—the home of the cowboy—has much to recommend it as a health resort. This strip of prairie and hill country is bounded on the north by the Canadian Pacific Railway and on the south by the international boundary line: its eastern boundary extends as far as Medicine Hat; its western boundary to the summit line of the Rockies and British Columbia, comprising in all an area of about 20,000 square miles. The plain here has an elevation above sea level of 2,700 ft., which gradually increases up to the entrance of the Crow's Nest Pass, where the elevation is 4500 ft. Calgary, the capital of Alberta, is itself 3500 ft. above sea level. With this gradual incline from a low to a high level altitude the patient can choose the locality which suits his particular case. In a long experience Kennedy knew of only two cases of phthisis originating in that country: one of acute tuberculosis with a strong hereditary taint, which proved fatal; the other, of the ordinary type, recovered without leaving the place. He claims for the climate of Southern Alberta a dry aseptic atmosphere and a dry soil, the greatest possible number of sunshiny days (90 per cent.), with cool nights. Patients can live there all the year round, and, with the exception of an occasional snowstorm, which may cover the prairie to a varying depth, nothing need interfere with their practically living in the saddle. The so-called Chinook wind has a remarkable influence over all this western section of Canada. It is a warm wind, which blows with varying intensity from west to south-west. McCaul, who describes it very graphically, speaks of its approach being heralded by the massing of dark clouds above the mountain tops, and a distinct wailing and rumbling from the passes and gorges. Its effect in winter is little short of miraculous. When the real Chinook blows the temperature often rises in a few hours from 20° below to 40° above zero. The snow which in the morning may have been a foot deep disappears, and before night everything is dripping; but in the space of a single day all the water is lapped up by the thirsty wind, and the prairie is so dry that a horse's hoof hardly makes an impression. The cases which have been most especially benefited by Alberta's climate are pulmonary tuberculosis in the earliest stage, although neurasthenics and anæmic women are likewise favourably affected to a marked degree. It is well known that delicate lads sent from the British Isles to this section of the north-west to work on the cattle ranches become in a year or two healthy and vigorous men, and are scarcely recognised on their return. Still farther west, and nearly midway between Calgary and the Pacific Coast, is the beautiful valley of Kamloops, another all-the-year-round resort which has much to commend it to those suffering from many forms of tuberculous disease. This picturesque valley, which lies between the Rocky Mountains and the Cascade Range, has a low altitude climate of 1100 ft., but is exceeding dry, showing an annual rainfall of only 11·05 inches, with an average of about seventy-five rainy days in the year. The rain soon disappears, the soil being light and gravelly. In this region we have an illustration of the local variability of climate recently pointed out by Bryce, who, in referring to the two not very distant localities of Vancouver and Kamloops, showed that whereas the former has an annual rainfall of 35 inches, the latter records but 11 inches and a decimal. The mean annual temperature of the valley of Kamloops is 46·03° F., the annual range being only 22·8°. The tuberculous patients who appear to be most benefited by a residence in Kamloops are those in whom there is a tendency to chronic congestion. Cases of bronchitis are likewise said to do well there. The climate can also be recommended for phthisical patients where cardiac disease exists as a complication.

That Canada is an exceptionally healthful country is the general testimony of the army and navy surgeons who have been stationed in Canada with the different regiments from the time of the conquest to the present day. Crawford, who was attached to one of the regiments stationed in Montreal many years ago, and who subsequently left the army and practised in this city, published elaborate and carefully-collected statistics to prove that few portions of the British Empire have a climate equal to that of Canada. In fact, his statistics prove conclusively that out of every 1000 of the troops stationed at the various garrisons throughout the empire, the percentage constantly ineffective from sickness was smaller in this country by 7 per cent. than at Gibraltar, which was then taken as the type. I think it can be satisfactorily proved that Canada is expressly fitted to develop a hardy race capable of great endurance. The races of the British Isles and the French race have certainly not degenerated here. Hingston proved this very conclusively some years ago by observations made upon the medical students attending the various schools in this city. He found that the lumbar strength of the British Canadian of the third generation exceeded by 20 lb. that of the recently-arrived English and Scotch students. But the French Canadian of the tenth generation did better than all by nearly 30 lb. Not only has the French Canadian increased in strength, but also in height and weight, over the original Normandy stock.

[Dr. Roddick next referred to the Canadian spas, mentioning particularly Banff, and continued:]

Banff, now a picturesque town magnificently situated in the heart of the Rocky Mountains, yet within the limits of that division of the North-West Territories known as Alberta, has become one of our noted health resorts, although frequented more on account of its remarkable thermal springs than for its climatic advantages. The town is built on the banks of the Bow and Spray rivers, two large glacier streams, and is surrounded by mountains towering many thousands of feet above the level of the sea. The winter is short, beginning in December and ending in February, and is much milder than Ontario. Very little rain falls, and the days, as a rule, are bright and cloudless. Prolonged periods of warm weather are experienced during winter. March and April are variable; May is warm and bright; June is the month in which the greatest rainfall occurs; July, August, September, and October are very warm and very dry, with cool nights. At all seasons, with the exception perhaps of June, the air is dry and notably aseptic.

[Dr. Roddick then gave an analysis of the springs and mentioned their therapeutic value. He then passed to consider medical education in Canada. He continued:]

MEDICAL EDUCATION IN CANADA.

The general question of medical education is one of great importance and of unceasing interest, nor is this interest confined to the profession; it is becoming universal. The needs of medical education are fortunately being more fully realised by those who on account of their wealth and influence are in a position to render that substantial assistance which is so requisite. The time was when every medical school was a purely proprietary concern, "run" for the money that was in it. We feel in Canada, and I think I can speak for the profession in the neighbouring republic, that this day is passed, that high-minded philanthropists like Sir Donald Smith, the late John Henry Molson, and others with us, and the Johns Hopkins, the Stanfords, the Vanderbilts, the Rockfellers, the Miss Garretts, and others with them are beginning to realise that unendowed instruction in medicine must lead to imperfect results, and that private endowment, in the absence of State aid, has become an absolute necessity to a proper medical training. I am not an advocate for State aid to universities, and I rejoice that the University to which I have the honour to belong is not so dependent, as it might thus be deprived of those gifts of private munificence to which I have just referred. All honour to those far-seeing, open-handed men and women who are giving of their abundance in order to elevate the standard of medical education, and by so doing benefit their kind. As Gould very tersely puts it in one of his clever articles: "I think our reliance must be upon private bequests, and these can be secured only as we interest the rich. We must never weary in showing the neglect of the greatest, most palpable, most certain means of doing good. There is a strange fatality in men, an unaccountable inability of seeing the need that lies nearest the good that is dearest. There is more money to-day devoted to astronomy than to the prevention of disease. It is positively wonderful to think that men should be more

Digitized by Google

interested in stars and constellations than in their bodies and their physiological life."

A question which is nowadays agitating the minds of those especially interested in medical education is the kind of groundwork which is likely to bear the most direct relation to the future studies of the medical student. I think it is now conceded by all that he is placed at a greater advantage who first passes through an arts or a science course. I am happy to be able to report that from 15 to 20 per cent. of those who are studying medicine in this country to-day have had a collegiate training in either arts or a science. Which of the two should the parent or guardian choose? Had I a son whose instincts were in the direction of medicine I think I should choose for him the science course. The late Professor Huxley thought it was a most self-evident proposition that the educational training for persons who proposed to enter the medical profession should be largely scientific; not merely or even principally because an acquaintance with the elements of physical and biological science is absolutely essential to the comprehension of human physiology and pathology, but still more because of the value of the discipline afforded by practical work in these departments in the process of observation and experiment, in inductive reasoning, and in manipulation. The subjects in the science curriculum might be specially selected for the future medical student. Of course, it may be said in favour of the arts course that many of the subjects, such as physics and chemistry, constitute part of the curriculum; but then calculate the loss to the future surgeon of that training of the hand and eye which would lead him up to be a skilled operator; or to the scientific physician whose complicated instruments of precision employed in the diagnosis of disease need some mechanical knowledge for both their use and repair. Besides, the number of those has been increasing in number and complexity with the increase of scientific knowledge. But can we not make a new departure? Can we not urge that a special scientific education be arranged by the university for those who desire to enter the medical profession? Such a course would embrace elementary Latin and Greek, French and German, physics, chemistry, biology, psychology, elementary mechanics, a practical laboratory course on electricity, and drawing. After two years' study this might entitle the successful candidate to the degree of Licentiate in Science. Something of this kind has been recently attempted in the University of McGill. By a special arrangement with the Faculty of Arts it is now possible for students to obtain the degree of B.A. along with M.D., C.M., after only six years of study. It has been decided to allow the primary subjects (anatomy, physiology, and chemistry) in medicine to count as subjects of the third and fourth years in arts. It follows, then, that at the end of four years' study a student may obtain his B.A. degree and have two years of his medical course completed. The last two years of study are, of course, devoted to the third and fourth year subjects in medicine. A certificate of Licentiate in Arts will be given along with the professional degree in medicine to those who previously to entrance upon their professional studies proper have completed examinations therein. By this plan, also, during the first two years of the arts course the medical student practically completes his studies in physics, chemistry, botany, and elementary psychology. This scheme is still in the experimental stage, but there is every reason to believe that it will result satisfactorily. What deters so many from taking a full course in arts or science before entering medicine is the length of time consumed before the doctorate degree is reached. I might state that the standard for the ordinary matriculation examination for entrance to medicine exacted by all universities and licensing boards in this country is, with one or two exceptions, very high. I doubt if the requirements in this way of the General Medical Council of Great Britain are any higher.

[Dr. Roddick here compared the Canadian medical schools with those of the United States and continued:]

In clinical teaching also we have made marked advances. A creation of the last few years is the clinical demonstrator, who takes small classes of students into the wards or the outdoor department of our hospitals, and gives them that "bedside instruction" which is so essential, leaving the clinical professor to deal with the full classes in the lecture or operating room. Thus each student is enabled personally to examine the case, to study the physiognomy of disease, and to make deliberate, thorough, and systematic examinations. He thus learns to use his special senses, and gets into careful habits of observation which once thoroughly acquired will be found to contribute largely to future success. With this in view, we encourage students to attend the out-patient department of the hospitals as early as the second year. In order to make the clinical instruction more complete and more thorough chemical and bacteriological laboratories have been added to the pathological departments of our hospitals. Thus it will be seen that laboratory methods everywhere prevail, all with the idea of developing the scientific spirit in students and of cultivating methods of thought with observation. The question sometimes arises, however, May the student not be getting too much of a good thing? Is it not possible that laboratory teaching may be overdone? because, as Welsh very truly says, "The student whose knowledge of a subject is derived exclusively from laboratory courses is likely to lose his perspective in details, to acquire only a fragmentary knowledge of the subject, to fail to comprehend the general bearing of observed facts; and not to acquire the general principles and systematic conceptions which are essential. Laboratory work should be accompanied and supplemented by the reading of text-books and by lectures." I am convinced that with us in Canada laboratory work is not overdone, but, on the contrary, in some departments needs and deserves further encouragement. I hope every laboratory teacher in the country realises that the object of a college is to give a good general education and not to make experts in various branches. I have long felt myself, however, that the didactic lectures were being unfairly dealt with. There is a feeling abroad that they should be practically elbowed out of sight. I think the didactic lecture has its place in the medical course; and while I quite feel that the old plan of compelling students to listen to five didactic lectures a week in all of the great subjects was a mistake, I still feel that a good lecturer can teach in this way a certain something which cannot be imparted by practical instruction or by recitations. The personal influence of a good lecturer very often makes an impression which nothing else can make; and if such lectures are made also demonstrative, as by the use of diagrams, the lantern, experiments, &c., they must of necessity fill a very important place in the medical course.

Hygiene is at last receiving in this country the attention which its importance demands; all medical schools in Canada have facilities for teaching it. In McGill University the scope of the teaching of hygiene has been vastly extended, thanks to the generous endowment of that department recently by the chancellor, Sir Donald Smith. The subject can now be taught in a scientific, and at the same time eminently practical, manner. There will be three teachers associated with the professor himself—namely, the heads of the Department of Practical Chemistry, of Pathology, and of Bacteriology. This is following very much the German system, also adopted by the University of Pennsylvania, the chemical and bacteriological aspects of the subject being really regarded as the most important. An extensive working museum, with sanitary apparatus of every kind, forms part of the scheme, and will doubtless add greatly to the efficiency of the course when it is completed. Should the experiment succeed you will be rejoiced to hear at no distant date that the other schools in Canada have followed the lead of their elder sister. I fear I have given you a very imperfect idea of medical education in Canada, and it may be charged against me that I have been partial in my description to my own university; but I assure you that such was furthest from my thoughts. The medical faculty of McGill University has the right of seniority, and might fairly, I think, be taken as a type of Canadian medical schools. Be assured there is no mean spirit of rivalry abroad. We are all working with one object only—the advancement of medicine in Canada. The teaching facilities of some medical schools in this country may be, and are, actually greater than others, owing to the munificence of citizens, and the school attached to McGill is, I am happy to say, in that position; but although assistance has been rendered in a general way, with two exceptions the chairs are still unendowed; yet we have great expectations, which we hope will be realised in the near future. Let us hope that our sister universities throughout Canada will be equally fortunate, so that before long we shall be able to report that we are all marching abreast equally equipped. The facilities for clinical teaching in the larger cities of Canada are admirable. Speaking for the city of Montreal, we have in the five general hospitals—the Hôtel Dieu, Montreal General, Notre Dame, Royal Victoria, and Western Hospitals—nearly

Digitized by Google

800 beds. The number of students attending the three medical schools was last session 646; and, considering that only about half—those of the third and fourth years—have access to the wards, there will be at least two beds for each student. The number of out-door patients attending the five hospitals daily would aggregate at least 300, so that there could be no possible cause for complaint regarding both the quantity and quality of clinical material available in this city.

While on the subject of hospitals I would take this opportunity of saying that the training schools attached to the larger English hospitals are in a very flourishing condition, and are found to contribute not a little towards the thoroughness of the practical teaching. It was my intention to have referred at some length to the whole question of nurses and nursing, but the limits of this address forbid. I might say, however, while as a profession we feel the absolute necessity for the training school and thoroughly appreciate the services of the well-trained nurse, both in hospital and in private practice, there is the fear that the supply may soon exceed the demand. A project is on foot now, however, which may delay, if not actually prevent, such a result. I refer to the recent establishment by that most estimable and charitable woman, the Countess of Aberdeen, of the Victorian Order of Nurses—another outcome of the Jubilee of our beloved Queen. Her Excellency's idea in establishing this Order is to supply the sparsely settled parts of our great north-west, the outlying districts of Canada generally, and the poor in towns and cities with nursing aid. In this great work hundreds of nurses will in time be employed. The scheme, which is purely non-sectarian, and appeals to all irrespective of nationality, when thoroughly worked out and more generally understood will become one of our national institutions. Let us wish it every success.

MEDICAL LEGISLATION IN CANADA.

Time will not permit of my discussing the subject of medical legislation in Canada at any length; and, besides, you will find it very fully treated in the excellent Souvenir or Local Guide prepared for you by the executive committee. In addition, I might explain, however, that when the British American provinces became federated in 1867, under the British North America Act, the governance of educational matters was taken away from the Federal authorities, and handed over to the provinces, each to look after them in its own way. In consequence we have since had a curious complexity of medical legislation, there being practically no uniformity amongst the provinces in regard to standard of study or qualification for practice. Each province has its own medical board or medical council, as the case may be, which has the power to grant licence to practise either after examination or on simply presenting the diploma of certain recognised universities. In the provinces of Ontario and British Columbia an examination is exacted; in the others the licence is given under certain restrictions on presentation of the degree, although in the Maritime Provinces an examining board is now about to be established. In this way, as can readily be seen, a Chinese wall is built round each province, and the frontier is carefully guarded, so that it is unsafe for a medical man to pass from one to the other unarmed with a licence because of the risk of fine or even imprisonment. Such a condition of affairs is hardly credible, and probably exists nowhere else to the same extent. What is the remedy? Two remedies have been suggested—either the establishment of a central examining board in each province with a uniform standard of matriculation and a uniformly high standard of curriculum which shall in time lead up to a general scheme of reciprocity; or, secondly, a Dominion Examining Board. The first scheme is at present under serious consideration, although there are many difficulties in the way of its accomplishment, none of which is insuperable, however, providing a spirit of conciliation prevails. The second alternative (a Dominion Examining Board) would in many respects be more desirable, because not only could the licentiate practise in any part of the Dominion, but he could register in Great Britain, and thus receive recognition all over the empire. As you are doubtless aware, we as a profession suffer in this country from being inhabitants of provinces which are confederated. In an enactment, now of some twelve years' standing, the British Medical Council decided in effect to recognise the degrees of universities situated in autonomous provinces only. As a consequence, Australians obtain privileges which are denied to us, being permitted to register in Great Britain without examination. We are being punished for belonging to a colony whose form of Government is recognised to be in advance of theirs and likely to be imitated by them. Let us give our Australian brethren a hint; if the confederation of your provinces be in contemplation, see to it that all matters of professional education are left in the hands of the Central Government, at least as far as qualification for registration is concerned. By so doing you will avoid the almost inextricable tangle in which we in Canada find ourselves. Let common school education go to the various provinces if you will, but for the profession of medicine (and doubtless law also) there should be a uniform standard of matriculation, a uniform curriculum of medical studies, and one Central Examining and Registering Board composed of the best men from all the universities. We hope in Canada to reach that ideal at no distant date; in fact, I have the very best authority for stating that it is not impossible of accomplishment. Some scheme of reciprocity first arranged would doubtless make the task less difficult, but, failing that, our duty is to arrange for some legislation which shall give our better and more ambitious students an opportunity of passing a Dominion Licensing Board (or whatever it may be called) which shall give the privilege of practising their profession, not only in any part of their native country, but in any part of the world over which the British flag flies. Such a scheme need not interfere in any way with the autonomy of the provinces. Each may still retain its Provincial Board for the purpose of examining and issuing licences to those candidates who are satisfied to practise their profession in the limited sphere of their own provinces. I think the legislators of this country will some day (and not far distant either) be induced to see that the system which at present obtains is unworthy of a great and growing country.

In conclusion, allow me to express the hope that the arrangements made by the executive committee for the entertainment of our guests may meet with appreciation and approval, and that the memories of the brief sojourn here may be all that is bright and happy. The loyalty and unanimity with which the profession throughout the Dominion has coöperated with us in Montreal to make this meeting of the British Medical Association a success from every point of view deserves and receives our heartiest thanks. We are also greatly indebted for the kind and ready assistance of the Dominion Government, the Quebec Government, and the Civic Government of Montreal. Our hands have been strengthened, and the cause we have so much at heart has been furthered, by the active goodwill of the country's official representatives. One word more. It is a good thing to be here to-day in the midst of this great gathering so full of power and vigour. The fruits of such a gathering should be tangible, enduring—not ephemeral, nor for to-day, but for all time. To our kinsmen from beyond the great seas let me express the earnest hope that in the future our kinship will be a more real and living thing than in the past. We are members of one great family, members one of another, in a peculiar and very real sense. Let that once be recognised and the statesman's task will be an easy one. In more than words has Canada shown herself worthy of her high heritage, worthy of a part in the Empire, worthy to share in its trials and triumphs. We who know her history can say with well-founded confidence:

> "So in the long hereafter this Canada shall be
> The worthy heir of British power and British liberty,
> Spreading the blessings of her sway to her remotest bounds,
> While with the fame of her fair name a continent resounds.
> True to her high traditions, to Britain's ancient glory,
> Of patient saint and martyr, alive in deathless story;
> Strong in their liberty and truth to shed from shore to shore
> A light among the nations till nations are no more."

CLAYBURY ASYLUM.—On Aug. 30th Dr. Collins, the chairman of the London County Council and a prominent member of the asylums committee, to whose advocacy the pathological laboratory for the London asylums is due, distributed the certificates of the Medico-Psychological Association for Proficiency in Mental Nursing to the Male and Female Staff. He delivered an interesting address, reviewing the treatment of insanity from the early days of "Bedlam" in 1653, when the victims of disease were imprisoned and ill-treated for being a "displeasure to God and an annoyance to the King's subjects." He urged upon nurses and attendants the cultivation of forbearance, gentleness, and graciousness in their dealings with the insane, that their duty was to extend human happiness and lessen human pain, and that kindness and softness of manner would go far to assist in the recovery of those whose lives had probably been, before a stern and relentless fate decreed otherwise, full of hope, energy, and happiness.

Address in Medicine:

BRITISH MEDICINE IN GREATER BRITAIN

Delivered at the Sixty-fifth Annual Meeting of the British Medical Association at Montreal, August–September, 1897,

BY WILLIAM OSLER, M.D., F.R.C.P. LOND.,
PROFESSOR OF MEDICINE, JOHNS HOPKINS UNIVERSITY, BALTIMORE.

THE MAKING OF GREATER BRITAIN.

GENTLEMEN,—To trace successfully the evolution of any one of the learned professions would require the hand of a master—of one who, like Darwin, could combine the capacity for patient observation with philosophic vision. In the case of medicine the difficulties are enormously increased by the extraordinary development which belongs to the history of the present century. The rate of progress has been too rapid for us to appreciate, and we stand bewildered, and, as it were, in a state of intellectual giddiness, when we attempt to obtain a broad comprehensive view of the subject. In a safer "middle flight" it is my purpose to dwell on certain of the factors which have moulded the profession in English-speaking lands beyond the narrow seas—of British Medicine in Greater Britain. Even for this lesser task (though my affiliations are wide and my sympathies deep) I recognise the limitations of my fitness, and am not unaware that in my ignorance I shall overlook much which might have rendered less sketchy a sketch necessarily imperfect.

Evolution advances by such slow and imperceptible degrees that to those who are part of it the finger of time scarcely seems to move. Even the great epochs are seldom apparent to the participators. During the last century neither the colonists nor the mother country appreciated the thrilling interest of the long-fought duel for the possession of this continent. The acts and scenes of the drama, to them detached, isolated, and independent, now glide like dissolving views into each other, and in the vitascope of history we can see the true sequence of events. That we can meet here to-day, Britons on British soil in a French province, is one of the far-off results of that struggle. This was but a prelude to the other great event of the eighteenth century, the revolt of the colonies and the founding of a second great English-speaking nation—in the words of Bishop Berkeley's prophecy, "Time's noblest offering." Surely a unique spectacle that a century later descendants of the actors of these two great dramas should meet in an English city in New France. Here the American may forget Yorktown in Louisberg, the Englishman Bunker's Hill in Quebec, and the Frenchman both Louisberg and Quebec in Chataquay, while we Canadians, English and French, in a forgiving spirit, overlooking your unseemly quarrels, are only too happy to welcome you to our country, this land on which, and for which, you have so often fought. Once, and only once, before in the history of the world could such a gathering as this have taken place. Divided though the Greeks were, a Hellenic sentiment of extraordinary strength united them in certain assemblies and festivals. No great flight of imagination is required to picture a notable representation of our profession in the fifth century B.C. meeting in such a colonial town as Agrigentum under the presidency of Empedocles. Delegates from the mother cities, brilliant predecessors of Hippocrates of the stamp of Damocedes and Herodicus, delegates from the sister colonies of Syracuse and other Sicilian towns, from neighbouring Italy, from far distant Massilia and from still more distant Pauticapæum and Istria. And in such an assemblage there would have been men capable of discussing problems of life and mind more brilliantly than in many subsequent periods, in proportion as the pre-Hippocratic philosophers in things medical had thought more deeply than many of those who came after them.

We English are the modern Greeks, and we alone have colonised as they did—as free people. There have been other great colonial empires—Phœnician, Roman, Spanish, Dutch, and French; but in civil liberty and in intellectual freedom Magna Græcia and Greater Britain stand alone. The parallel so often drawn between them is of particular interest with reference to the similarity between the Greek settlements in Sicily and the English plantations on the Atlantic coast. Indeed, Freeman says: "I can never think of America without something suggesting Sicily, or of Sicily without something suggesting America." I wish to use the parallel only to emphasise two points, one of difference and one of resemblance. The Greek colonist took Greece with him. Hellas had no geographical bounds. "Massilia and Obia were cities of Hellas in as full a sense as Athens or Sparta." While the emigrant Britons changed their sky, not their character, in crossing the great sea, yet the home-stayers had never the same feelings towards the plantations as the Greeks had towards the colonial cities of Magna Græcia. If, as has been shrewdly surmised, Professor Seely was Herodotus re-incarnate, how grieved the spirit of the "Father of History" must have been to say of Englishmen, "Nor have we even now ceased to think of ourselves as simply a race inhabiting an island off the northern coast of the continent of Europe." The assumption of gracious superiority, which, unless carefully cloaked, smacks just a little of our national arrogance, is apt to jar on sensitive colonial nerves. With the expansion of the empire, and the supplanting of a national by an imperial spirit, this will become impossible. That this sentiment never prevailed in Hellas, as it did later in the Roman empire, was due largely to the fact that in literature, in science, and in art the colonial cities of Greece early overshadowed the mother cities. It may be because the settlements of Greater Britain were things of slower growth, that it took several generations and several bitter trials to teach a lesson the Greeks never had to learn. The Greek spirit was the leaven of the old world, the workings of which no nationality could resist. Thrice it saved Western civilisation, for it had the magic power of leading captivity captive, and making even captive conquerors the missionaries of culture. What modern medicine owes to it will appear later. "The love of science, the love of art, the love of freedom, vitally correlated to each other and brought into organic union," were the essential attributes of the Greek genius (Butcher). While we cannot claim for the Anglo-Saxon race all of these distinctions, it has in a high degree that one which in practical life is the most valuable, and which has been the most precious gift of the race to the world—the love of freedom.

> "Of freedom in her regal seat
> Of England."

It would carry one too far afield to discuss the difference between the native Briton and his children scattered so widely up and down the earth. In Canada, South Africa, Australia, and New Zealand types of the Anglo-Saxon race are developing which will differ as much from each other and from the English as the American does to-day from the original stock; but amid these differences can everywhere be seen those race qualities which have made us what we are—"courage, national integrity, steady good sense, and energy in work." At a future meeting of the Association, perhaps in Australia, a professional Sir Charles Dilke, with a firm grasp on the subject, may deal with the medical problems of Greater Britain in a manner worthy of the address in medicine. My task, as I mentioned at the outset, is much less ambitious.

THE INFLUENCE OF GREECE ON BRITAIN.

Could someone with full knowledge patiently analyse the characteristics of British medicine he would find certain national traits sufficiently distinct for recognition. Three centuries cannot do very much—and that period has only just passed since the revival of medicine in England—but the local conditions of isolation, which have been singularly favourable to the development of special peculiarities in the national character, have not been without effect on the medical profession. I cannot do more than touch upon a few features, not distinctive, but illustrative—features which will be useful as indicating the sources of influence upon Greater Britain in the past, and which may perhaps be suggestive as to lines of progress in the future. Above the fireplace in Sir Henry Acland's study are three panelled portraits of Linacre, Sydenham, and Harvey; the scroll upon them reads *Literæ, Praxis, Scientia*. To this great triumvirate, as to the fountain heads, we may trace the streams of inspiration which have made British medicine what it is to-day. Linacre, the type of the literary physician, must ever hold a unique place in the annals of our profession. To him was due in great measure the revival of Greek thought in the

Digitized by Google

sixteenth century in England, and in the last Harveian Oration Dr. Payne has pointed out his importance as a forerunner of Harvey. He made Greek methods available; through him the art of Hippocrates and the science of Galen became once more the subject of careful, first-hand study. Linacre, as Dr. Payne remarks, "was possessed from his youth till his death by the enthusiasm of learning. He was an idealist, devoted to objects which the world thought of little use." Painstaking, accurate, critical, hypercritical perhaps, he remains to-day the chief literary representative of British medicine. Neither in Britain nor in Greater Britain have we maintained the place in the world of letters created for us by Linacre's noble start. It is true that in no generation since has the profession lacked a man who might stand unabashed in the temple at Delos; but, judged by the fruits of learning, scholars of his type have been more common in France and Germany. Nor is it to our credit that so little provision is made for the encouragement of these studies. For years the reputation of Great Britain in this matter was sustained almost alone by the great Deeside scholar, the surgeon of Banchory, Francis Adams, the interpreter of Hippocrates to English students. In this century he and Greenhill have well maintained the traditions of Linacre. Their work, and that of a few of our contemporaries, among whom Ogle must be specially mentioned, has kept us in touch with the ancients. But by the neglect of the study of the humanities, which has been far too general, the profession loses a very precious quality.

While in critical scholarship and in accurate historical studies British medicine must take a second place, the influence of Linacre, exerted through the Royal College of Physicians and the old Universities, has given to the humanities an important part in education, so that they have moulded a larger section of the profession than in any other country. A physician may possess the science of Harvey and the art of Sydenham, and yet there may be lacking in him those finer qualities of heart and head which count for so much in life. Pasture is not everything, and that indefinable, though well understood, something which we know as breeding is not always an accompaniment of great professional skill. Medicine is seen at its best in men whose faculties have had the highest and most harmonious culture. The Lathams, the Watsons, the Pagets, the Jenners, and the Gairdners have influenced the profession less by their special work than by exemplifying those graces of life and refinements of heart which make up character. And the men of this stamp in Greater Britain have left the most enduring mark: Beaumont, Bovell, and Hodder, in Toronto; Holmes, Campbell, and Howard, in this city; the Warrens, the Jacksons, the Bigelows, the Bowditches, and the Shattucks, in Boston; Bard, Hossack, Francis, Clark, and Flint in New York; Morgan, Shippen, Redman, Rush, Coxe, the elder Wood, the elder Pepper, and the elder Mitchell in Philadelphia—Brahmins all, in the language of the greatest Brahmin among them—Oliver Wendell Holmes—these, and men like unto them, have been the leaven which has raised our profession above the dead level of a business. The *literæ humaniores*, represented by Linacre, revived Greek methods, but the faculty at the end of the sixteenth and the beginning of the seventeenth centuries was in a slough of ignorance and self-conceit, and not to be aroused even by Moses and the prophets in the form of Hippocrates and the fathers of medicine. In the pictures referred to Sydenham is placed between Linacre and Harvey, but science preceded practice, and Harvey's great Lumleian lectures were delivered before Sydenham was born. Linacre has been well called by Payne Harvey's intellectual grandfather. "The discovery of the circulation of the blood was the climax of that movement which began a century and a half before with the revival of Greek medical classics and especially of Galen" (Payne). Harvey returned to Greek methods and became the founder of modern experimental physiology and the great glory of British scientific medicine. The demonstration of the circulation of the blood remains in every detail a model research. I shall not repeat the oft-told tale of Harvey's great and enduring influence, but I must refer to one feature which until lately has been also a special characteristic of his direct successors in Great Britain. Harvey was a practitioner and a hospital physician. There are gossiping statements by Aubrey to the effect that "he fell mightily in his practice" after the publication of the "De Motu Cordis," and that his "therapeutic way" was not admired; but to these his practical success is the best answer. It is remarkable that a large proportion of all the physiological work of Great Britain has been done by men who have become successful hospital physicians and surgeons. I was much impressed by a conversation with Professor Ludwig in 1884. Speaking of the state of English physiology, he lamented the lapse of a favourite English pupil from science to practice; but he added, "While sorry for him, I am glad for the profession in England." He held that the clinical physicians of that country had received a very positive impress from the work of their early years in physiology and the natural sciences. I was surprised at the list of names which he cited—among them I remember Bowman, Paget, Savory, and Lister. Ludwig attributed this feature in part to the independent character of the schools in England, to the absence of the university element, so important in medical life in Germany, but, above all, to the practical character of the English mind, the better men preferring an active life in practice to a secluded laboratory career. Thucydides it was who said of the Greeks that they possessed "the power of thinking before they acted and of acting too." The same is true in a high degree of the English race. To know first what has to be done, then to do it, comprises the whole philosophy of practical life. Sydenham (*Angliæ lumen*, as he has been well called) is the model practical physician of modern times. Linacre led Harvey back to Galen, Sydenham to Hippocrates. The one took Greek science, the other not so much Greek medicine as Greek methods, particularly intellectual fearlessness, and a certain knack of looking at things, Sydenham broke with authority and went to nature. It is an extraordinary fact that he could have been so emancipated from dogmas and theories of all sorts. He laid down the fundamental proposition, and acted upon it, that "all diseases should be described as objects of natural history." To do him justice we must remember, as Dr. John Brown says, "in the midst of what a mass of errors and prejudices, of theories actually mischievous, he was placed, at a time when the mania of hypothesis was at its height, and when the practical part of his art was overrun and stultified by vile and silly nostrums."

Sydenham led us back to Hippocrates; I would that we could be led oftener to Sydenham. How necessary to bear in mind what he says about the method of the study of medicine. "In writing, therefore, such a natural history of diseases, every merely philosophical hypothesis should be set aside, and the manifest and natural phenomena, however minute, should be noted with the utmost exactness. The usefulness of this procedure cannot be easily overrated as compared with the subtle inquiries and trifling notions of modern writers, nor can there be a shorter, or, indeed, any other way of coming at the morbific causes, or of discovering the curative indications, than by a certain perception of the peculiar symptoms. By these steps and helps it was that the father of physic, the great Hippocrates, came to excel, his theory being no more than an exact description or view of Nature. He found that Nature alone terminates diseases, and works a cure with a few simple medicines, and often enough with no medicine at all." Well, indeed, has a recent writer remarked: "Sydenham is unlike every previous teacher of the principles and practice of medicine in the modern world." Sydenham—not Linacre or Harvey—is the model British physician, in whom were concentrated all these practical instincts upon which we lay such stress in the Anglo-Saxon character. The Greek faculty which we possess of thinking and acting has enabled us, in spite of many disadvantages, to take the lion's share in the great practical advances in medicine. The three greatest scientific movements of the century have come from Germany and France. Bichat, Laennec, and Louis laid the foundation of modern clinical medicine; Virchow and his pupils of scientific pathology; while Pasteur and Koch have revolutionised the study of the causes of disease; and yet the modern history of the art of medicine could almost be written in its fulness from the records of the Anglo-Saxon race. We can claim almost every practical advance of the very first rank—vaccination, anæsthesia, preventive medicine, and antiseptic surgery—the "captain jewels in the carcanet" of the profession, beside which can be placed no others of equal lustre.

THE INFLUENCE OF AUTHORITY IN MEDICINE.

One other lesson of Sydenham's life needs careful conning. The English Hippocrates, as I said, broke with authority. His motto was

> "Thou, Nature, art my goddess; to thy law
> My services are bound."

Digitized by Google

Undue reverence for authority as such, a serene satisfaction with the *status quo*, and a fatuous objection to change have often retarded the progress of medicine. In every generation, in every country, there had been, and ever will be, *laudatores temporis acti*, in the bad sense of that phrase, not a few of them men in high places, who have lent the weight of a complacent conservatism to bolster up an ineffectual attempt to stay the progress of new ideas. Every innovator, from Harvey to Lister, has been made to feel its force. The recently issued Life of Thomas Wakley is a running commentary on this spirit, against the pricks of which he kicked so hard and so effectually. But there are signs of a great change. The old universities and the colleges, once the chief offenders, have been emancipated, and remain no longer, as Gibbon found them, steeped in port and prejudice. The value of authority *per se* has lessened enormously, and we of Greater Britain have perhaps suffered as the pendulum has swung to the other extreme. Practice loves authority, as announced in "the general and perpetual voice of men" (Hooker). Science must ever hold with Epicharmus that a judicious distrust and a wise scepticism are the sinews of the understanding. And yet the very foundations of belief in almost everything relating to our art rests upon authority. The practitioner cannot always be the judge, the responsibility must often rest with the teachers and investigators, who can only learn in the lessons of history the terrible significance of the word.

In the treatment of fever the fetters of a thousand years were shattered by Sydenham—shattered only to be riveted anew. How hard was the battle in this century against the entrenched and stubborn foe. Listen to the eloquent pleadings of Stokes, pleading, as did Sydenham, against authority and against the bleedings, the purgings, and sweatings of fifty years ago. "Though his hair be grey and his authority high he is but a child in knowledge and his reputation an error. On a level with a child, so far as correct appreciation of the great truths of medicine is concerned, he is very different in other respects; his powers of doing mischief are greater; he is far more dangerous. Oh! that men would stoop to learn, or at least cease to destroy." The potency of human authority among "the powers that be" was never better drawn than by the judicious Hooker in his section on this subject. "And this not only with the 'simpler sort,' but the learneder and wiser we are the more such arguments in some cases prevail with us. The reason why the simpler sort are moved with authority is the conscience of their own ignorance; whereby it cometh to pass that having learned men in admiration, they rather fear to dislike them than know wherefore they should allow and follow their judgments. Contrariwise with them that are skilful, authority is much more strong and forcible, because they only are able to discern how just cause there is why to some men's authority so much should be attributed. For which cause the name of Hippocrates, no doubt, were more effectual to persuade even such men as Galen himself than to move a silly empiric."[1] Sydenham was called "a man of many doubts," and therein lay the secret of his great strength.

MEDICINE IN AMERICA: TO 1820.

Turning now to the main question of the development of this British medicine in Greater Britain I must at once acknowledge the impossibility of doing justice to it. I can only indicate a few points of importance, and I must confine my remarks chiefly to the American part of Greater Britain. We may recognise three periods corresponding to three distinct waves of influence: the first from the early migrations to about 1820, the second from about 1820 to 1860, and the third from about 1860 to the present time. The Colonial settlements were contemporaneous with the revival of medicine in England. Fellow students of Harvey at Cambridge might have sailed in the *Mayflower* and the *Arbella*. The more carefully planned expeditions usually enlisted the services of a well-trained physician, and the early records, particularly of the New England colonies, contain many interesting references to these college-bred men. Giles Firman, who settled in Boston in 1632, a Cambridge man, seems to have been the first to give instruction in medicine in the new world. The parsons of that day had often a smattering of physic, and illustrated what Cotton Mather called an "angelical conjunction." He says: "Ever since the days of Luke the Evangelist skill in physic has been frequently professed and practised by persons whose more declared business was the study of divinity." Firman himself finding physic "but a meane helpe" took orders. These English physicians in the New England colonies were scholarly, able men. Roger Chillingworth, in Hawthorne's "Scarlet Letter," has depicted them in a sketch of his own life: "Made up of earnest, studious, thoughtful, quiet years, bestowed faithfully for the increase of knowledge; faithfully, too, for the advancement of human welfare; men thoughtful for others, caring little for themselves, kind, just, true, and of constant if not warm affections"—a singularly truthful picture of the old colonial physician.

Until the establishment of medical schools—University of Pennsylvania, 1763; King's College (afterwards Columbia), 1767; and Harvard, 1782—the supply of physicians for the colonies came from Great Britain, supplemented by men trained under the old apprentice system and of colonists who went to Edinburgh, Leyden, and London for their medical education. This latter group had a most powerful effect in moulding professional life in the pre-revolutionary period. They were men who had enjoyed not alone the instruction, but often the intimate friendship, of the great English and European physicians. Morgan, Rush, Shippen, Bard, Wistar, Hossack, and others had received an education comprising all that was best in the period, and had acquired the added culture which can only come from travel and wide acquaintance with the world. Morgan, the founder of the medical school of the University of Pennsylvania, was away seven years, and before returning had taken his seat as a corresponding member of the French Academy of Surgery, besides having been elected a Fellow of the Royal Society. The War of Independence interrupted temporarily the stream of students, but not the friendship which existed between Cullen and Fothergill and their old pupils in America. The correspondence of these two warm friends of the colonies testifies to the strong professional intimacy which existed at the time between the leaders of the profession in the old and new worlds. But neither Boerhaave, Cullen, nor Fothergill stamped colonial medicine as did the great Scotsman, John Hunter. Long weary centuries separated Harvey from Galen; not a century elapsed from the death of the great physiologist to the advent of a man in whose phenomenal personality may be seen all the distinctive traits of modern medicine, and the range of whose mighty intellect has had few, if any, equals since Aristotle. Hunter's influence on the profession of this continent, so deep and enduring, was exerted in three ways. In the first place, his career as an army surgeon, and his writings on subjects of special interest to military men, carried his work and ways into innumerable campaigns in the long French wars and the War of Independence. Hunter's works were reprinted in America as early as 1791 and 1793. In the second place, Hunter had a number of most distinguished students from the colonies, among whom were two who became teachers of wide reputation. William Shippen, the first Professor of Anatomy in the University of Pennsylvania, lived with Hunter on terms of the greatest intimacy. He brought back his methods of teaching and some measure of his spirit. With the exception of Hewson and Home Hunter had no more distinguished pupil than Philip Syng Physick, who was his house surgeon at St. George's Hospital and his devoted friend. For more than a generation Physick had no surgical compeer in America, and enjoyed a reputation equalled by no one save Rush. He taught Hunterian methods in the largest medical school in the country, and the work of his nephew (Dorsey) on surgery is very largely Hunter modified by Physick. But in a third and much more potent way the great master influenced the profession of this continent. Hunter was a naturalist to whom pathological processes were only a small part of a stupendous whole, governed by law, but which could never be understood until the facts had been accumulated, tabulated, and systematised. By his example, by his prodigious industry, and by his suggestive experiments he led men again into the old paths of Aristotle, Galen, and Harvey. He made all thinking physicians naturalists; he lent a dignity to the study of organic life, and re-established a close union between medicine and the natural sciences. Both in Britain and Greater Britain he laid the foundation of the great collections and museums, particularly those connected with the medical schools. The Wistar-Horner and the Warren Museums originated with men who had been greatly influenced by Hunter. He was, moreover, the intellectual father of that interesting group of men on this side of the Atlantic who, while practising as physicians, devoted

[1] Ecclesiastical Polity, Book ii., vii., 2.

Digitized by Google

much time and labour to the study of natural history. In the latter part of the last century and during the first thirty years of this the successful practitioner was very often a naturalist.

I wish that time permitted me to do justice to the long list of men who have been devoted naturalists and who have made contributions of great value. Benjamin Smith Barton, David Hossack, Jacob Bigelow, Richard Harland, John D. Godman, Samuel George Morton, John Collis Warren, Samuel L. Mitchell, J. Aiken Meigs, and many others have left the records of their industry in their valuable works, and in the Transactions of the various societies and academies. In Canada many of our best naturalists have been physicians, and collections in this city testify to the industry of Holmes and McCullough. I was regretting the humanities a few minutes ago, and now I have to mourn the almost complete severance of medicine from the old natural history. To a man the most delightful recollections of whose studentship are the Saturdays spent with a preceptor who had a Hunterian appetite for specimens—anything from a trilobite to an acarus,—to such a one across the present brilliant outlook comes the shadow of the thought that the conditions of progress will make impossible again such careers as those of William Kitchen Parker and William Carmichael McIntosh. Until about 1820 the English profession of this continent knew little else than British medicine. After this date in the United States the ties of professional union with the old country became relaxed, owing in great part to the increase in the number of home schools and in part to the development of an American literature. To 1820, 114 native medical books of all kinds had been issued from the press, and 131 reprints and translations, the former English, the latter almost exclusively French (Billings). Turning for a few minutes to the conditions of the profession in Canada during this period, I regret that I cannot speak of the many interesting questions relating to the French colonies. I may mention, however, that with the earliest settlers physicians had come, and among the Jesuits, in their devoted missions, there are records of *donnés* (laymen attached to the service) who were members of the profession. One of these, René Goupil, suffered martyrdom at the hands of the Iroquois.[2] Between the fall of Quebec in 1759 and 1820 the English population had been increased by the settlement of Upper Canada, chiefly by United Empire Loyalists from the United States, and after the war of 1812 by settlers from the old country. The physicians in the sparsely-settled districts were either young men who sought their fortunes in the new colony or were army surgeons who had remained after the revolutionary war or the war of 1812. The military element gave for some years a very distinctive stamp to the profession. These surgeons were men of energy and ability, who had seen much service and were accustomed to order, discipline, and regulations. Sabine, in his "History of the Loyalists," refers to the Tory proclivities of the medical men, and says that they were not so much disturbed as the lawyers and clergymen. Still a good many of them left their homes "for conscience' sake"; and Canniff, in his "History of the Profession in Upper Canada," gives a list of those known to have been among the United Empire Loyalists. The character of the men who controlled the profession of the new colony is well shown by the proceedings of the Medical Board, which was organised in 1819. Dr. Macaulay and Dr. Widmer, both army surgeons, were the chief members. The latter, who has well been termed the father of the profession in Upper Canada, a man of the very highest character, did more than anyone else to promote the progress of the profession, and throughout his long career his efforts were always directed in the proper channels. In looking through Canniff's most valuable work one is much impressed by the sterling worth and mettle of the old army surgeons, who in these early days formed the larger part of the profession. The minutes of the Medical Board indicate with what military discipline the candidates were examined, and the percentage of rejections has probably never been higher in the history of the province than it was in the first twenty years of the existence of the Board.

One picture on the canvas of those early days lingers in the memory, illustrating many of the most attractive features of a race which has done much to make this country what it is to-day. Widmer was the type of the dignified old army surgeon, scrupulously punctilious and in every detail regardful of the proprieties of life. "Tiger" Dunlop may be taken as the very incarnation of that restless, roving spirit which has driven the Scots broadcast upon the world. After fighting with the Connaught Rangers in the war of 1812, campaigning in India, clearing the Sangur of tigers—hence his sobriquet "Tiger"—lecturing on medical jurisprudence in Edinburgh, writing for *Blackwood*, editing the *British Press* and the *Telescope*, introducing "Beck's Medical Jurisprudence" to English readers, and figuring as director and promoter of various companies, this extraordinary character appears in the young colony as "Warden of the Black Forest" in the employ of the Canada Company. His life in the backwoods at Gairbraid, his "Noctes Ambrosianæ Canadensis," his famous "Twelve Apostles," as he called his mahogany liquor-stand (each bottle a full quart), his active political life, his remarkable household, his many eccentricities,—are they not all pourtrayed to the life in the recently issued "In the Days of the Canada Company"?

AMERICA: 1820–1860.

Turning now to the second period, we may remark in passing that the nineteenth century did not open very auspiciously for British medicine. Hunter had left no successor, and, powerful as had been his influence, it was too weak to stem the tide of abstract speculation with which Cullen, Brown, and others flooded the profession. No more sterile period exists than the early decades of this century. Willan, a great naturalist in skin diseases, with a few others, save it from utter oblivion. The methods of Hippocrates, of Sydenham, and of Hunter had not yet been made available in everyday work. The awakening came in France, and such an awakening! It can be compared with nothing but the renaissance in the sixteenth and seventeenth centuries, which gave us Vesalius and Harvey. "Citizen" Bichat and Broussais led the way, but Laennec really created clinical medicine as we know it to-day. The discovery of auscultation was only an accident—of vast moment, it is true—in a systematic study of the correlation of symptoms with anatomical changes. Louis, Andral, and Chomel extended the reputation of the French school, which was maintained to the full until the sixth decade, when the brilliant Trousseau ended a long line of Paris teachers, whose audience had been world-wide.

The revival of medicine in Great Britain was directly due to the French. Bright and Addison, Graves and Stokes, Forbes and Marshall Hall, Latham and Bennett, were profoundly affected by the new movement. In the United States Anglican influence did not wane until after 1820. Translations of the works of Bichat appeared as early as 1802, and there were reprints in subsequent years, but it was not until 1823 that the first translation of Laennec—a reprint of Forbes's edition—was issued. Broussais's works became very popular in translations after 1830, and in the journals from this time on the change of allegiance became very evident. But men rather than books diverted the trend of professional thought. After 1825 American students no longer went to Edinburgh and London, but to Paris, and one can say that between 1830 and 1860 every teacher and writer of note passed under the Gallic yoke. The translations of Louis's works and the extraordinary success of his American pupils—a band of the ablest young men the country has ever seen—added force to the movement. And yet this was a period in which American medical literature was made up largely of pirated English books, and the systems, encyclopædias, and libraries, chiefly reprints, testify to the zeal of the publishers. Stokes, Graves, Watson, Todd, Bennett, and Williams furnished Anglican pap to the sucklings as well as strong meat to the full grown. In spite of the powerful French influence the text-books of the schools were almost exclusively English. In Canada the period from 1820 to 1860 saw the establishment of the English universities and medical schools. In Montreal the agencies at work were wholly Scottish. The McGill Medical School was organised by Scotsmen, and from its inception has closely followed Edinburgh methods. The Paris influence, less personal, was exerted chiefly through English and Scottish channels. The Upper Canada schools were organised by men with English affiliations, and the traditions of Guy's, St. Bartholomew's, St. Thomas's, St. George's, and of the London Hospital rather than those of Edinburgh, have prevailed in Toronto and Kingston. The local French influence on British medicine in Canada has been very slight. In the early decades of the century, when the cities were smaller, and the intercourse between the French and English somewhat closer, the

Digitized by Google

reciprocal action was more marked. At that period English methods became somewhat the vogue among the French; several very prominent French Canadians were Edinburgh graduates. Attempts were made in the medical journals to have communications in both languages, but the fusion of the two sections of the profession was no more feasible than the fusion of the two nationalities, and the development has progressed along separate lines.

AMERICA, 1860–1897.

The third period dates from about 1860, when the influence of German medicine began to be felt. The rise of the Vienna school was for a long time the only visible result in Germany of the French renaissance. Skoda, the German Laennec, and Rokitansky, the German Morgagni, influenced English and American thought between 1840 and 1860, but it was not until after the last date that Teutonic medicine began to be felt as a vitalising power, chiefly through the energy of Virchow. After the translation of the "Cellular Pathology" by Chance (1860) the way lay clear and open to every young student who desired inspiration. There had been great men in Berlin before Virchow, but he made the town on the Spree a Mecca for the faithful of all lands. From this period we can date the rise of German influence in the profession of this continent. It came partly through the study of pathological histology under the stimulus given by Virchow, and partly through the development of the specialities, particularly diseases of the eye, of the skin, and of the larynx. The singularly attractive courses of Hebra, the organisation on a large scale in Vienna of a system of graduate teaching, designed especially for foreigners, and the remarkable expansion of the German laboratories combined to divert the stream of students from France. The change of allegiance was a deserved tribute to the splendid organisation of the German Universities, to the untiring zeal and energy of their professors, and to their single-minded devotion to science for its own sake.

MEDICINE IN AUSTRALASIA.

In certain aspects the Australasian settlements present the most interesting problems of Greater Britain. More homogeneous, thoroughly British, isolated, and distant, they must work out their destiny with a less stringent environment than, for example, surrounds the English in Canada. The traditions are more uniform, and, of whatever character, have filtered through British channels. The professional population of native-trained men is as yet small, and the proportion of graduates and licentiates from the English, Scottish, and Irish Colleges and Boards guarantees the dominance of old country ideas. What the maturity will show cannot be predicted, but the vigorous infancy is full of "crescent promise." On looking over the files of Australian and New Zealand journals one is impressed with the monotonous similarity of the diseases in the Antipodes to those of Great Britain and of this continent. Except in the matter of parasitic affections and snake bites, the nosology presents few distinctive qualities. The proceedings of the four Intercolonial Congresses indicate a high level of professional thought. In two points Australia has not progressed as other parts of Greater Britain. The satisfactory regulation of practice, so early settled in Canada, has been beset with many difficulties. Both in the United States and in Australia the absence of the military element, which was so strong in Canada, may in part at least, account for the great difference which has prevailed in this matter of the State licence. The other relates to the question of ethics, to which one really does not care to refer, were it not absolutely forced upon the attention in reading the journals. Elsewhere professional squabbles, always so unseemly and distressing, are happily becoming very rare, and in Great Britain and on this side of the water we try at any rate to wash our dirty linen at home. In the large Australian cities differences and dissensions seem lamentably common. Surely they must be fermented by the atrocious system of election to the hospitals, which plunges the entire profession every third or fourth year into the throes of a contest in which the candidates have to solicit the suffrages of from 2000 to 4000 voters. Well indeed might Dr. Batchelor, in his address to the Fourth Intercolonial Congress, say: "It is a scandal that in any British community, much less in a community which takes pride in a progressive spirit, such a pernicious system should survive for an hour."

MEDICINE IN HINDUSTAN.

Of India, of "Vishnu-land," what can one say in a few minutes? Three thoughts at once claim recognition. Here, in the dim dawn of history, with the great Aryan people, was the intellectual cradle of the world. To the Hindus we owe a debt which we can at any rate acknowledge; and even in medicine many of our traditions and practices may be traced to them, as may be gathered from that most interesting "History of Aryan Medical Science," by the Thakore Sahib of Gondal. Then there arises the memory of the men who have done so much for British medicine in this great empire. Far from their homes, far from congenial surroundings, and far from the stimulus of scientific influences, Annesley and Ballingall, Twining, Morehead, Waring, Parkes, Cunningham, Lewis, Vandyke Carter, and many others have nobly upheld the traditions of Harvey and of Sydenham. On the great epidemic diseases how impoverished would our literature be in the absence of their contributions. But then there comes the thought of "the little done, the undone vast," when one considers the remarkable opportunities for study which India has presented. Where else in the world is there such a field for observation in cholera, leprosy, dysentery, the plague, typhoid fever, malaria, and in a host of other less important maladies. And what has the British Government done towards the scientific investigation of the diseases of India? Until recently little or nothing, and the proposal to found an institute for the scientific study of disease has actually come from the native chiefs. The work of Dr. Hankin and of Professor Haffkine, and the not unmixed evil of the brisk epidemic of plague in Bombay, may arouse the officials to a consciousness of their shortcomings. While sanitary progress has been great, as shown in a reduction of the mortality from 69 per mille before 1857 to 15 per mille at present, many problems are still urgent, as may be gathered from Dr. Harvey's Presidential Address in the Proceedings of the Indian Medical Congress. That typhoid fever can be called the "scourge of India," and that the incidence of the disease should remain so high among the troops, points to serious sanitary defects as yet unremedied. As to the prevalence of venereal disease among the soldiers, an admission of nearly 500 per mille tells its own tale. On reading the journals and discussions one gets the impression that things are not as they should be in India. There seems to be an absence of proper standards of authority. Had there been in each Presidency during the past twenty years well-equipped Government laboratories in charge of able men, well trained in modern methods, the contributions to our knowledge of epidemic diseases might have been epoch-making.

THE FUTURE OF MEDICINE IN GREATER BRITAIN.

In estimating the progress of medicine in the countries comprising Greater Britain the future rather than the present should be in our minds. The strides which have been taken during the past twenty years are a strong warrant that we have entered upon a period of exceptional development. When I see what has been accomplished in this city in the short space of time since I left I can scarcely credit my eyes. The reality exceeds the utmost desires of my dreams. The awakening of the profession in the United States to a consciousness of their responsibilities and opportunities has caused unparalleled changes, which have given an impetus to medical work which has already borne a rich harvest. Within two hundred years who can say where the intellectual centre of the Anglo-Saxon race will be? The mother country herself has only become an intellectual nation of the first rank within a period altogether too short to justify a prediction that she has reached the zenith. She will probably reverse the history of Hellas, in which the mental superiority was at first with the colonies. At the end of the next century ardent old-world students may come to this side, "as o'er a brook," seeking inspiration from great masters, perhaps in this very city; or the current may turn towards the schools of the great nations of the south. Under new and previously unknown conditions the Africander, the Australian, or the New Zealander may reach a development before which even the "glory that was Greece" may pale. Visionary as this may appear, it is not one whit more improbable to-day than would have been a prophecy made in 1797 that such a gathering as the present would be possible within a century on the banks of the St. Lawrence.

Meanwhile to the throbbing vitality of modern medicine the two great meetings held this month, in lands so widely distant, bear eloquent testimony. Free, cosmopolitan, no longer hampered by the dogmas of schools, we may feel a just pride in a profession almost totally emancipated from the bondage of error and prejudice. Distinctions of race, nationality, colour, and creed are unknown within the portals

Digitized by Google

of the temple of Æsculapius. Dare we dream that this harmony and cohesion so rapidly developing in medicine, obliterating the strongest lines of division, knowing no tie of loyalty but loyalty to truth—dare we hope, I say, that in the wider range of human affairs a similar solidarity might ultimately be reached? Who can say that the forges of Time will weld no links between man and man stronger than those of religion or of country? Some son of Beor, touched with a prophetic vision, piercing the clouds which now veil the eternal sunshine of the mountain top, some spectator of all time and all existence (to use Plato's expression) might see in this gathering of men of one blood and one tongue a gleam of hope for the future—of hope, at any rate, that the great race, so dominant on the earth to-day, may progress in the bonds of peace—a faint glimmer, perhaps, of the larger hope of humanity of the day when "the common sense of most shall hold a fretful world in awe." But these, I fear, are the dreams of the closet student who knows not the world or its ways. There remains for us, Greater Britons, of whatsoever land, the bounden duty to cherish the best traditions of our fathers, and particularly of the men who gave to British medicine its most distinctive features; of the men, too, who found for us the light and liberty of Greek thought—Linacre, Harvey, and Sydenham—those "ancient founts of inspiration," and models for all time in literature, science, and practice.

ABSTRACT OF THE

Address in Surgery:

THE SURGEON OF OLD IN WAR.

Delivered at the Sixty-fifth Annual Meeting of the British Medical Association at Montreal, August-September, 1897,

BY W MITCHELL BANKS, M.D. EDIN.,

FELLOW AND MEMBER OF COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; SURGEON TO THE LIVERPOOL ROYAL INFIRMARY; EMERITUS PROFESSOR OF ANATOMY, UNIVERSITY COLLEGE, LIVERPOOL.

GENTLEMEN,—I am indeed greatly honoured by having to deliver to you to-day an Address in Surgery. Fortunately for me the title is a wide one, and I shall take advantage of that fact to diverge from the strict consideration of surgical disease, and shall offer you instead a brief sketch of some of the most notable work done of old by a body of members of our profession who have never received their due reward—those, namely, who have devoted their lives to the succour of the sick and the wounded in war.

MILITARY SURGEONS IN THE ROMAN ARMY.

Twelve months ago my friend, Dr. Barnes, of Carlisle, ex-President of this Association, made me acquainted with a remarkable paper by the late Sir James Simpson, entitled, "Was the Roman Army provided with medical officers?"—a paper exhibiting such profound learning, so charmingly written, and so little known, that I need not make any apology for acquainting you with some of its chief points of interest. The most careful investigations have failed to make out from their writings whether the Romans regularly appointed physicians and surgeons to their armies or not, although nearly every other question relating to their military organisation has been treated of, sometimes very fully. Curiously enough, what little information we possess on the subject comes mainly from mortuary or from votive tablets. Borcovicus, in Northumberland,—now called Housesteads—was one of the principal stations on the line of Hadrian's wall. Here, about seventy years ago, was found a monumental tablet, now in the Newcastle Museum. On it is the following inscription:—

D M	D(IIS) M(ANIBUS)
ANICIO	ANICIO
INGENUO	INGENUO
MEDICO	MEDICO
ORD COH	ORD(INARIO) COH(ORTIS)
I TUNGR	PRIMAE TUNGR(ORUM)
VIX AN XXV	VIX(IT) AN(NOS) XXV

The First Tungrian Cohort is known to have been present at the battle of the Mons Grampius, and to have served at Castlecary, at Cramond near Edinburgh, in Cumberland, and at Housesteads. The tablet is highly ornamented, and antiquarians hold that a rabbit and round bucklers carved in the upper part, which are emblems of Spain, show that the young military doctor was probably a native of that country. From various works treating of Roman inscriptions, Simpson was enabled to find that four more tablets, in which surgeons of cohorts are mentioned, existed. They were found at Rome. One of them is a votive tablet, the inscription upon which intimates that it was dedicated by Sextus Titius Alexander to Æsculapius and to the safety of his fellow soldiers. It was cut in the year of the consulship of F. Flavius Sabinus, which is known to have been A.D. 83. As the Roman legion consisted of ten cohorts, it is interesting to know that there were not only medical officers attached to each cohort, but also one attached to the legion—a sort of surgeon-colonel, as we should call him nowadays. Three tablets have been discovered in which the *medicus legionis* is mentioned. One found at Verona was a tablet raised by Scribonia Faustina to her dearest husband J. Caelius Arrianus, medical officer to the Second Italian Legion, who died at the age of forty-nine years and seven months. Furthermore, Simpson routed out of Mommsen's Latin inscriptions of Naples a tablet, now in the Dresden collection, which was found in the Elysian fields near Baiae, close to the Portus Julius, which was the station of a division of the Imperial fleet. The inscription tells that M. Satrius Longinus, *medicus duplicatorius* to the Trireme Cupid, and the heirs of those freed by Julia Veneria erected the tablet to the manes of that deserving lady. The term *duplicatorius* means that by reason of long or meritorious service he was entitled to double pay and rewards. These little gleanings from Simpson's paper show what an interesting one it is, and one is astonished at the labour that must have been expended in digging up the information contained in it.

AMBROISE PARÉ. ROBERT CLOWES.

[Mr. Banks here gave an outline of the work of Ambroise Paré (1517-1590) in the course of which he remarked: "The world will ever believe in a glorious trio—Paré, the Frenchman, who invented the ligature; Morton, the American, who discovered anæsthetics; and Lister, the Englishman, who introduced antiseptics." He then passed on to Robert Clowes (1540?-1604) who served in France in the army commanded by the Earl of Surrey, and was afterwards for several years in the navy. He finally settled down in London, where he was very successful in practice, and was made surgeon to the Queen. He wrote several works in English, of which the most important is entitled, "A profitable and necessarie Booke of Observations for all those that are burned with the flame of gunpowder, &c., and also for curing of wounds made with musket and caliver shot, and other weapons of war commonly used at this day both by sea and land." Mr. Banks continued:]

PETER LOWE.

Contemporary with Clowes was a most interesting character—Maister Peter Lowe—who was born in Scotland about 1550, and lived some sixty or sixty-five years, reaching well into the seventeenth century. Like many of his countrymen he went to France when very young, where he lived, for some say ten, some twenty years. Then he returned to Glasgow, where he lived and died a citizen of much renown, having obtained in 1599 from King James the Sixth a charter for the Faculty of Physicians and Surgeons of Glasgow, which he thus founded. A few years ago Dr. Finlayson published a most charming account of Maister Peter. His most important work is termed "A Discourse of the whole art of chirurgery, compiled by Peter Lowe, Scottishman, Doctor in the Faculty of Chirurgerie at Paris, and ordinary Chyrurgion to the French King and Navarre." The first edition dated from 1597, and is one of the earliest, if not the very earliest, work embracing the whole art of surgery published in English. It is clear that Lowe must have seen a good deal of military service abroad, being "Chirurgion Major to the Spanish regiments two years at Paris, and since that time following the king of France my maister in the warrs." In his day, as we have seen, the surgical world was still greatly exercised about gunshot wounds and burning by gunpowder as it was believed that they were injuries of quite a peculiar and very poisonous character. Lowe, however, treats of them with great good sense. Thus: "*Of Wounds done by Gun-shot.*—These wounds come indifferently to all parts of

Digitized by Google

our body whereof there are divers opinions; some think that there is a venenosity in the powder, and burning in the bullet, which is false, for the things whereof the powder is ordinarily made, as Brimstone, Saltpeter, coales of divers sorts of trees, Water, Wine and Aquavitæ, have no venenosity in them; likewise there is no burning in the bullet, for if the bullet of lead being shot a great way, should burne, through heat would be melted itself. I have cured divers within these thirty yeares of divers nations which have followed the warres in Fraunce and other countries, in the which I have found no more difficulty than in any other contused wounds." Here, again, we have a most important advance made by a military surgeon, for only those who are acquainted with the medical literature of Lowe's time can understand the ridiculous views then held about gunshot wounds and the dreadful consequences to the patients which followed from them. We have seen that Paré lived between 1517 and 1590. and that Peter Lowe was in France between 1570 and 1580; consequently, he probably learned all about the ligature for the arrest of hæmorrhage. When treating of amputations he describes the whole process of the operation up to the removal of the limb. Then he says: "One of the Assisters shall put the extreamities of his fingers on the great vains and arteries to stay them from bleeding till the Chyrurgion either knit or cauterise them one after another. Where there is putrefaction we stay the flux of blood by Cauters actuals, and where there is no putrefaction, malignitie, nor humour venomous we use the legator."

WOODALL'S "VIATICUM."

In 1628 appeared the first work in England specially devoted to military and naval surgery. Some eleven years later a second edition appeared, and this is its title—"Viaticum, being the Pathway to the Surgeon's Chest, containing chirurgical instructions for the younger sort of surgeons imployed in the service of his Majestie or for the Common-Wealth upon any occasion whatsoever intended for the better curing of wounds made by Gunshot," by John Woodall. A perusal of the "Viaticum" shows that Woodall was a very practical surgeon and an eminently religious man, and the way in which he mixes up pills and piety is sometimes very diverting. After some excellent general advice to the surgeon's mate, including a warning against "being given and dedicated to the Pot and Tobacco-pipe in an unreasonable measure," he enumerates the instruments for the Surgeon's Chest, including among others Catlings, Rasours, Trapans, Trafine, Lavatories, Cauterising Irons, Storks bills, Ravens bills, Crowes bills, Terebellum, Probes or flamules, Glister Sirings, and (what would have utterly damned his book in the present day) "one bundle of small German instruments." Then comes a list of medicines under the heading Unguentum, Aqua, Sol, Oleum, Chemicall Oyles, Syrups, Conserva, Electuariæ, and so on, winding up with a list of the Simples and of the Herbs and Roots most fit to be carried. A long and careful description of the uses of the instruments and drugs follows, and then come chapters on wounds, aposthumes, fractures, dislocations, amputation, scurvy, the plague, gangrene, and other topics. He observes that the cauterising irons had gone somewhat out of fashion, and he did not use them much himself "because of the feare they put the Patient into and for speech of people who are ready to scandalise an Artist upon each light occasion." In amputation, moreover, they are "now wholly forborne for reasons aforesaid, and for that a more pleasant course is known better for the patient and the Artist by making a ligature upon the veine, wound, or artery, which is the binding of each end thereof, being first caught and holden with some fit instrument, and tied with a sure and strong thread." Woodall advances the cure of wounds a distinct step, once more putting us under an obligation to the soldier-surgeon. This he does by sharply attacking all through his works the inordinate and meddlesome use of strong caustics.

RICHARD WISEMAN.

I wish I had time to give you a proper account of the adventurous life of Richard Wiseman, who has been termed the Father of English Surgery, and that not without reason. Born in 1620, dying in 1676, he lived in the time of Charles I., of the Commonwealth, and of Charles II. He was a naval surgeon to begin with, serving in the early part of his life in the Dutch navy. Being, however, a devoted Royalist he served with the armies of Charles I., and after his death went into exile with his son in France. He was present at the battle of Worcester, where he was taken prisoner, and afterwards confined in Lambeth House for awhile. During the Commonwealth he was naturally under a cloud, and even went off for three years to serve in the Spanish navy. At the restoration the King did not forget his old surgeon, who had done and suffered so much in his service, but appointed him his surgeon-in-ordinary and afterwards serjeant-surgeon. The first edition of his work, printed in 1672, is quite a small book, and is entitled "A Treatise of Wounds," but it afterwards expanded into a very large volume.

Wiseman believed in the need for giving stimulants to a man who was in the habit of taking them if that man was in a dire strait. After describing the parlous case of a certain patient, it seems that the "man swooned and complained that he could not live without wine. I complied with his desire; he drank again as he pleased, his sickness went off, his wound digested, and he cured. This I have often seen in some of our Dunkirkers at sea, who drank extraordinarily and who were full of drink in our sea fights. I could scarce ever cure them without allowing them wine, and thereby their spirits were kept up and I had the liberty to bleed them as I thought fit." From this it is clear that the old saying about Dutch courage has a distinct origin in fact. But if the unhappy Batavians were liable to be bled at once by the lance of the enemy and the lancet of the surgeon, one can hardly wonder at their taking something to keep their spirits up. When speaking of gunshot wounds he insists upon the bullet being searched for and extracted at once. "The part is at first dressing, with what diligence you can, to be cleared of all such Foreign Bodies as have made violent Intrusion into it, while the patient is warm with the heat of Battel, and the wound fresh and very little altered by either Air or Accidents, so that less pain must necessarily follow upon the extraction. In the *Armada Naval de Dunquerque*, where we Chirurgeons were oft employed in this Service, we after every fight went together visiting one another's wounded men. Amongst us it was thought a great shame if any of this work of Extraction was there to be done. It hath been the cause of the death of many a brave Souldier, and every Battel produces instances of it, to the discredit of our profession." This is good surgery, and I think it must have been a fine spectacle to have seen these old surgeons walking round to see each other's patients and learning how best to mend their mistakes.

BARON LARREY.

[Mr. Banks here referred at some length to Baron Larrey, "the Chirurgien-en-Chef de la Grande Armée, the friend and body surgeon of Napoleon, the greatest military surgeon that ever lived," of whom he said in concluding,]

The retreat from Moscow called into play all Larrey's resources, and many an interesting story could be told of his efforts. Think of the awful battle of the Borodino, where under Larrey's own direction 200 amputations were performed, where there were neither couches nor blankets nor covering of any kind, and where the food consisted of horseflesh, cabbage stalks, and a few potatoes; think of cold so intense that the instruments requisite for the operations too often tumbled from the powerless hands of the French surgeons. Larrey succeeded in getting over the Beresina with the Imperial Guard, but discovered that the requisites for the sick and wounded had been left on the other side. At once he re-crossed the river only to find himself in the midst of a furious struggling crowd. He was on the point of being crushed to death when providentially the soldiers recognised him. No sooner did they do so than they carried him across the river in their arms, with the cry, "Let us save him who saved us!" and forgot their own safety in their desire to preserve the man whose tender kindness they had so often experienced. Following his adored master through victory and defeat, Larrey at last stood at night on the field of Waterloo alone, except for some medical officers and the wounded who lay groaning around them. Down upon them came a squadron of Prussian lancers. Expecting no quarter he fired his pistols at them and galloped away. They shot his horse and sabred him as he lay on the ground. Leaving him apparently dead they went off; but he recovered his senses, and tried to crawl by cross roads into France. Again he was seized by another detachment of Prussian cavalry. They robbed him promptly of all he possessed, and took him before a superior officer, who ordered him to be shot. What a reward from a soldier to one whose life had been passed in succouring soldiers! About a quarter of an hour before the sentence was to be carried out a surgeon-major recognised Larrey.

Digitized by Google

He had attended with deep interest a course of lectures which Larrey had delivered in Berlin six years previously. The prisoner was brought before Bulow, and finally presented to Blücher, whose son in the Austrian campaign had been badly wounded and captured by the French, and who owed his life to Larrey's exertions. Larrey's honourable and glorious life terminated in 1842. Napoleon, when he made his will at St. Helena, wrote in it: "I bequeath to the Surgeon-in-Chief of the French Army, Larrey, 100,000 francs. He is the most virtuous man I have ever known." From Napoleon's lips the words of free spontaneous, ungrudging praise such as this rarely fell.

PESTILENCE MORE DEADLY THAN THE SWORD.

In the middle of last century, while surgery had distinctly improved, the gross neglect of the Government and the pig-headed obstinacy of the generals was such that our unfortunate soldiers and sailors were hardly any better off than they were in the days of Paré. It has been maintained that Smollett, in the appalling picture of naval life as witnessed in the miserable expedition to Carthagena which he drew in "Roderick Random," and which is known to have been the record of his own experience as a surgeon's mate, grossly exaggerated the evils thereof. I do not believe this. Look at the awful and unsuccessful expedition to Portobello in 1726, when nearly the whole of the crews of the ships were destroyed by fever three times over; where two admirals, ten captains, fifty lieutenants, and about 3000 to 4000 inferior officers and men perished without striking a blow. Look at the taking of Havannah in 1762. The Earl of Albemarle took with him in the fleet 11,000 soldiers. Between June and the middle of October, when Cuba was ours, we had lost 560 men by wounds and 4708 by sickness. At the end of the Seven Years' War a statement was drawn up in the "Annual Register" for 1763 from which it appeared that in all the naval battles of that war there were but 1512 sailors and marines killed, while 133,738 had died from disease or were "missing." Look even at the end of last century and consider the wretched and disgraceful Walcheren campaign. Never did our poor soldiers fight with more gallantry than in that campaign, only to perish beside Dutch ditches and canals from fever and ague and dysentery.

MILITARY COURAGE.

As we have just seen, Baron Larrey's whole life shows that, while absolutely devoted to the work of his profession, he displayed a cool courage on the field of battle not less heroic than the more dazzling deeds of his fellow combatant officers. Not less does it mark the military surgeon of the present day. Have you ever heard of Surgeon Thomson who, during the Crimean War, when the army marched off after the battle of the Alma, volunteered, with his servant, John McGrath, to remain behind on the open field with 500 terribly wounded Russians, and passed three awful days and nights—these two Englishmen alone—among foreign foes, some dead, some dying, and none able to raise a hand to help themselves? Have you ever heard of Assistant-Surgeon Wolseley, of the 20th Regiment, who, at the battle of Inkerman, had quietly established his field hospital in that awful place, the Sandbag Battery? When the 150 men, who were all that remained of its defenders, were forced to desert it, about 100 of them fell back in one direction, and in that they found, at thirty paces from them, a Russian battalion blocking their path. There was not a combatant officer left, so the assistant surgeon took command. He had not even a sword with him, but, laying hold of a firelock with a fixed bayonet on it, he spoke a few words to the men within range of his voice, and told them that what they now had to fight for was not victory but life. Then he gave them the word of command: "Fix bayonets, charge, and keep up the hill." The soldiers answered him with a burst of hurrahs, sprang forward to the charge, and the next instant were tearing through the thickest of the Russians. One half of these reached the other side alive. Have you ever heard of Surgeon Landon, who was shot through the spine while attending to the wounded on Majuba Hill? His legs were paralysed, but he caused himself to be propped up, and continued his merciful work till his strength ebbed away. When unable for more he quietly said: "I am dying, do what you can for the wounded." Have you ever heard of Surgeon-Captain Whitchurch, who gained the Victoria Cross at the beleaguering of Chitral for the most determined courage in endeavouring to save the life of Major Baird? Yes, you have, for last year at Carlisle you gave him the gold medal of the Association, the highest honour which our Association can give to its members. There died the other day a certain Surgeon-General Reade, C.B., V.C. During the siege of Delhi, while attending to the wounded at the end of one of the streets of the city, a party of rebels advanced from the direction of the bank, and having established themselves in the houses in the street commenced firing from the roofs. The wounded were thus in very great danger, and would have fallen into the hands of the enemy had not Surgeon Reade drawn his sword, and, calling upon a few soldiers who were near to follow, succeeded under a very heavy fire in dislodging the rebels from their position. Surgeon Reade's party consisted of about ten in all, of whom two were killed and five or six wounded. Surgeon Reade was a Canadian, and the son of a colonel of the Canadian Militia. Of the 118 wearers of the Victoria Cross 14 are surgeons—nearly 12 per cent. of the whole number. They stand in the proportion of 9½ per cent. of all the officers of the army, so at all events they have contributed not less than their fair share of the deeds of valour which alone can win that glorious distinction.

THE ARMY MEDICAL SERVICE TO-DAY.

I have diverged from the beaten track common to the givers of addresses such as this to tell you what splendid men have been the military and naval surgeons of old, who not merely did their duty nobly and courageously as such, but who have in their day enormously contributed to the advance of the art of surgery. I have done it with a purpose; with the hope of attracting more strongly than ever the sympathy and help of this great Association to their military brethren in a critical juncture of their history. To-day Her Majesty's Government cannot induce candidates to come forward for the medical service of the Queen's army. And why? Because it has persistently treated the Army Medical Department meanly and shabbily. To-day the Government of India can secure the services of the pick of our newly-fledged doctors for its army. And why? Because it has always treated the Indian Medical Service liberally and generously. I am not going to enter into the reasons for this; I desire merely to emphasise one point—namely, that money is not at the bottom of this difficulty. The soldier-surgeons of to-day are the same men now that they were in the days of William Clowes, who winds up his book, as I shall my address, with these verses:—

"When valiant Mars, with brave and warlike band,
In foughten field with sword and shield doth stand,
May there be mist a surgeon that is good,
To salve your wounds and eke to stay your bloud.

"To cure you sure he will have watchful eie,
And with such wights he means to live and die,
So that againe you must augment his store,
And having this he will request no more."

A FURTHER COMMUNICATION ON THE OCCURRENCE OF A HITHERTO UNDESCRIBED FORM OF CHRONIC NEPHRITIS UNASSOCIATED WITH ALBUMINURIA.[1]

BY D. D. STEWART, M.D.,

PROFESSOR IN THE PHILADELPHIA POLYCLINIC AND POST-GRADUATE SCHOOL; PHYSICIAN TO THE EPISCOPAL HOSPITAL, &c.

IN two previous communications on this subject[2] I drew attention to a small group of personally studied cases of evident chronic nephritis, in all of which, with quite similar clinical characters, the urine was persistently albumin-free during the period in which they were under observation. I regarded these cases as representing, perhaps, a not uncommon, although hitherto unrecognised, variety of nephritis, the symptoms of which in all agreed more or less in certain important particulars. The character of these

[1] Read before the Association of American Physicians at Washington, May, 1897.

[2] On the Occurrence of a Form of Chronic Bright's Disease Other than Typical Fibroid Kidney, without Albuminuria, Transactions of the First Pan-American Congress, and the American Journal of the Medical Sciences, December, 1893. Further Remarks on the Occurrence of a Form of Non-albuminous Nephritis other than Typical Fibroid Kidney, Transactions of the College of Physicians, 1894, and the "Medical News," April 14th, 1894.

Digitized by Google

were such, I remarked, as to place them clinically without the boundary of the well-known varieties of the so-called Bright's diseases, such as chronic desquamative nephritis and the fibroid or granular kidney.

Concerning the absence of albumin in chronic nephritis I pointed out that it had been long known that cases of fibroid kidney could occur, especially in the early stages of the malady, without albumin in the urine, or with albumin existing, if constant, only in traces, or to be found in certain portions of the twenty-four-hours urine. I said that the occurrence of typical granular kidney without albuminuria had been first noted by Wilks, of Guy's Hospital, nearly half a century ago, but it was Mahomed, some three decades later, who especially investigated cases of this phase of the disease, describing a considerable number of them in Guy's Hospital Reports for 1879 and 1880–81. But it was doubtful if many of Mahomed's cases, such as I cited, were actually cases of renal disease, though they could be properly included in the category of chronic Bright's disease as Mahomed employed the term. The symptoms of numerous of these were in the main referable to other organs, and in a minority of those in which a necropsy was obtained the kidneys were stated to be normal.

Cases of chronic nephritis occurring other than at the degenerative period of life, in which, without evident indications of accompanying arterial sclerosis, and in which the symptoms were so frankly of kidney origin as to indicate that the affection was beyond everything else a primary renal disease, to which changes in the vascular system were subsidiary and in all probability a result of a toxic blood state induced by the imperfect functioning of the damaged kidneys, were not recognised by Wilks or by Mahomed, and their even rare occurrence is still regarded by many as apocryphal. If such a case with pronounced symptoms is accepted to be one of nephritis, it is commonly thought that the absence of albumin, if such is proved, is either an ephemeral condition or that the ailment as yet is too limited in its seat and too early in its course for albumin to appear. It was to such cases as these that I especially directed attention, reporting a small group in which the symptoms were so distinct and separable from those of the well-recognised forms of nephritis as to indicate for it a distinct pathology. As to these symptoms I stated in my former paper that "with an oliguria as persistent and as marked in certain cases as in the most outspoken type of chronic parenchymatous nephritis, and with a urine as concentrated, yet with absence of cardiac debility and of dropsy to indicate its source, there occur as grave continuous symptoms of renal inadequacy—those, indeed, of pronounced uræmia. These are associated, too, as in chronic parenchymatous nephritis, with as marked diminution in urinary solids, notably diminution in urea and mineral ingredients, indicating undoubted secretory involvement; yet totally unlike what is distinctive of parenchymatous nephritis, albumin is so persistently absent from the urine, even with the existence of the aggravated symptoms of renal incompetency, as to clearly indicate that its presence need form no part of the assemblage of symptoms or have any relation to the morbid condition."

There must exist some radical pathological difference in the renal condition of such cases in which, whether with or without the presence of albumin in the urine, but with the constant occurrence of casts, and more or less steady diminution in the excretion of urea, symptoms of retention of nitrogenous waste are totally absent, even though there may be present a typical retinitis Brightii, indicating that the disease is in an advanced stage. I recently studied several cases of this sort for Dr. L. Webster Fox, in three of which symptoms referable to the kidney were totally absent. Headache did not occur, vertigo was uncommon, and the general health was quite well preserved. The patients regarded themselves as in good health apart from failing vision. In all Dr. Fox had encountered what he termed "non-albuminuric retinitis." In one case "the right eye was a mass of retinal hæmorrhages, with here and there colloid degeneration, so characteristic of morbus Brightii"; in the other cases a quite similar retinal condition was evident. Albumin had been found absent in a number of examinations made both by Dr. Fox and the attending physician of the cases. In the urine of one of the three I found in several examinations a trace of albumin; this was evident to the heat test, and trichloracetic acid gave an instantaneous sharp ring. In the others traces of albumin were absent to heat. These cases clinically rather fell into the category of those described by Wilks and by Mahomed, in which, perhaps, with extensive renal fibrosis, the excretion of toxic products was not far from the normal. Of the personally studied cases I reported, unfortunately but one has remained under observation to the present. The others were studied for one month in one case, three months in another, and from six months to four years in the remainder. Whether any of those that disappeared from observation have died in the interim, or, if living, changes have occurred in the character of the symptoms, in all save one, a brother of the case specially detailed, is quite unknown to me. Of the pathological conditions in the kidney of this case (Case 2 of the series described) I am able to make a report. This is of special interest, since the case may be regarded to be clinically a good example of this group.

The patient was a man, aged thirty-four years.[3] He first came under observation in the early part of 1893. Symptoms of his ailment had then existed for about two years. These were, briefly, more or less severe headaches and spells of vertigo. There had been from the first more or less prostration of strength, with incapacity for physical or mental exertion. This physical weakness had greatly increased in the last two years. But slight continuous exercise of mind or body induced severe headache, with vertigo and a sensation of great body weariness. There had been a tendency to more or less loin tire, and often to actual ache. There was also disturbed sleep, during which night terrors were common and limited clonic spasms occurred. The blood-pressure was habitually very high, the sphygmograms showing always a pulse of markedly raised tension. During the early period in which he was under observation a strictly vegetable diet, on which he was placed for a few weeks, greatly lowered blood-pressure, so that it became practically normal. This diet could not be continued on account of the dyspeptic symptoms originated by the food and the marked oxaluria so induced. The patient had lost 20 lb. in weight during the first two years of his ailment. This loss had not been regained. There had been no decided anæmia evident. Blood examinations made at intervals commonly showed a nearly normal blood-count. The skin was more or less habitually dry, and the complexion the past three years had been of a decidedly sallow hue. Debility, headaches, and vertigo were so prominent in this case, and these and other symptoms were always so aggravated on exertion, that although previously when in good health he had led a most active life he had been compelled to abandon his pursuits and become against his will a valetudinarian. Remedial measures had been of no permanent value for the relief of the symptoms. The urine had always been free from albumin to the present, excepting immediately succeeding the reni-puncture and excision of the small portion of the kidney. The urine had from the first been habitually much diminished in amount. When he first came under observation his habits were, as now, very methodical, and taking almost daily the same quantity of food and fluid the urine, measured for seven or more consecutive days, at intervals of a month, stood steadily between 700 and 800 c.c. The past year between 500 and 600 c.c. were more common. The amount voided in twenty-four hours not being known a single specimen as concerns colour, specific gravity, and absence of albumin would be regarded as normal. Even under thyroid extract and other remedies, the use of which tends to increase nitrogenous output, urea excretion had been very low, rarely exceeding 15 grammes. It commonly, estimated over long periods, ran between 13 and 15 grammes, about half the normal output for a person of his weight on the diet employed. Uric acid elimination was normal; at times it was a trifle high; the chlorides, as in all of these cases, were, as with the urea, habitually diminished in amount.[4] Microscopically the urine was found to invariably contain cylindroids, commonly in some amount. Hyaline casts were usual, and granular-hyaline, or finely granular, were not rare. Occasionally epithelial casts are found. Free uric acid and calcium oxalate crystals are common. As the specimens examined microscopically were commonly those of the mixed twenty-four-hours urine, which had stood for some little time after voiding, the presence of these could not be regarded as of significance. It is, however, a fact worthy of note that in all of these cases calcium oxalate and free uric acid crystals were frequently

[3] For more detailed history of this case see the American Journal of the Medical Sciences, December, 1893, p. 665.

[4] Diminished output of chlorine, in face of a normal or lessened HCl secretion, as had been ascertained in this and in several other of the cases, is of special significance, as was remarked in my previous paper.

Digitized by Google

seen in the specimens examined shortly after voiding. Irritability of the bladder, such as is usual with a free output of uric acid of the oxalates, had never been present. So much was this absent here that the patient not only never arose at night to urinate, but almost never emptied the bladder oftener than two or three times in the twenty-four hours. As in the other cases, albumin was never present in any of the examinations in amount to be detected by the application of the most reliable of all methods for its detection—heat, and the subsequent employment of acetic acid. By the more refined and less accurate tests, such as trichloracetic acid, the urine gave no instantaneous reaction. Commonly, with the employment of a super-saturated solution, a response only occurred at the expiration of from one half minute to several minutes, and then was slight in character. This, as I have elsewhere shown, is usual in all normal urines. My own urine and that of several other healthy individuals working in my laboratory, often tested coincidently, commonly showed a more marked response to trichloracetic acid.[5] Recently I was fortunate in securing a section from one of the kidneys in this patient for pathological study. This opportunity was suggested by the results obtained by Reginald Harrison in his cases recently reported, in which reni-puncture, and slitting a too tightly distended capsule in cases of extreme congestion of the kidney, occurring in the course of nephritis, had been followed by decided symptomatic relief. Although slight benefit was to be expected from such a procedure in this case, and but scant hope of it extended, the patient acquiesced, and Dr. Keen exposed one of the kidneys, depleted it by spearing, slit the capsule, and subsequently removing a small section of the organ for histological examination. The kidney was of normal size, but extremely hyperæmic. Despite this congestion, immediately before etherisation a specimen of urine obtained was still found to be free from albumin, although cylindroids abounded and hyaline casts were moderately numerous. For several weeks succeeding operation the urine contained albumin, as might be supposed. During this time there were abundant blood-corpuscles, blood-casts, and a profusion of epithelial, granular, and hyaline casts present in all specimens. The albumin gradually diminished in amount, and finally disappeared at the end of a month. Although the patient was somewhat buoyed with hope no benefit followed the operation. On the contrary, there has recently been an aggravation in his symptoms. The specimen removed was submitted to Dr. A. O. J. Kelly for examination who reported as follows: "The bloodvessels are distended and generally filled with blood. The intima in some few isolated places shows a slight proliferation of the endothelial lining. The media is thickened and stains rather homogeneously. It is, however, the adventitia that is especially involved. It is greatly thickened, and from it as a focus there proceed in various directions radiations of homogeneously staining connective tissue. In some places this perivascular connective-tissue overgrowth extends quite a little distance from the vessel, and it is here and there the seat of a slight round cell infiltration, though usually this is not evident and is never marked. This connective-tissue overgrowth is also present in areas in which no blood-vessels can be seen, but it is doubtless connected with blood-vessels that do not appear in the section. It is especially evident about blood-vessels in the neighbourhood of the glomeruli. The capsule of Bowman is associated in the process; it is thickened and rarely, if ever, shows any cellular infiltration. Thus originating about the blood-vessels near the glomeruli, involving the capsule of Bowman, this sclerosis spreads to a limited extent and surrounds the uriniferous tubules in the neighbourhood. The epithelial lining of the capsule of Bowman is frequently proliferated, and in some instances is free, doubtlessly artificially produced. Many of the convoluted tubules show a slight degree of degeneration; the epithelial cells are more granular than is normal; in many instances the lumen of the tubule is filled, and not rarely the nuclei stain imperfectly, exceptionally failing to take the stain at all. Not rarely formations resembling casts are seen. There are other more extensive areas of sclerosis in which the bands of connective tissue are much thicker, and in the midst of which the uriniferous tubules are smaller, not a few atrophic, and now and then one is seen obliterated. In a few places there is a very marked proliferation of the epithelial lining of the glomeruli and great thickening of the capsule of Bowman. From this latter the connective tissue overgrowth extends quite a distance surrounding the uriniferous tubules. The tufts of bloodvessels in the glomeruli are usually distended. In those glomeruli, however, about which there is such an excessive overgrowth of connective tissue they are diminished in size and at times quite atrophic. Exceptionally one notes a roundish area faintly fibrillar, containing not a few slightly staining round cells, the whole being suggestive of an obliterated glomerulus or blood-vessel." Microscopic sections of the kidney were submitted to Professor William H. Welch, of the Johns Hopkins Medical School, who reported in substance that he could confirm Dr. Kelly's observations of chronic interstitial changes as stated. The changes, according to Dr. Welch, although of slight extent, were unquestionably evident, and consisted of new growths of connective tissue about certain of the blood-vessels and some of the glomeruli, with atrophy here and there of a few tubes and a few glomeruli. Here and there also he noted a slight thickening of the intima of the blood-vessels.

In discussing in my first paper the probable pathological renal condition which underlay these cases I remarked that although the assemblage of symptoms was typical of no distinct form of chronic nephritis their trend was suggestive of granular kidney. But they had in common several points, the mingling of which in granular kidney has before been undescribed, such as absence of marked cardio-vascular change and of dropsy, with habitual diminution in the amount of urine and in the urinary solids, and especially in urea, together with the presence of obtrusive signs of a toxic blood state. Unfortunately, we know too little of the intimate physiological processes occurring in the kidneys in health and disease to more than conjecture as to the mode of production of symptoms from what to us is evident in the post-mortem condition. Although the gross changes present in this kidney may not be regarded as sufficiently marked in any one direction to readily explain the symptomatic condition, they are, in certain particulars at least, suggestive. In first reporting these cases I remarked as to the pathological renal condition, that there might be present glomerular changes of the nature of thickening of the capsule of the Malpighian tufts and of the afferent vessels, which could account for the diminution in the amount of urine voided—a symptom common in these cases, and not rare in others of supposed granular kidney in which dropsy is absent. Mahomed had thought that absence of albumin in certain cases of chronic nephritis might be due to a similar thickening of the vessels of the tufts, through which it would be difficult for albumin to pass, and also to thickening of Bowman's capsule, preventing distension of the vessels. It is significant, at least, that such thickening of vessels and of Bowman's capsule is, according to Dr. Kelly, usual in the specimen. Whether, however, it exists to such a general extent as to cause obvious symptoms, otherwise apparently inexplicable, is questionable. The absence of numerous granular, and especially of epithelial, casts, was strongly against decided changes in the tubules, and yet, as in all, the habitual imperfect elimination in nitrogenous waste, with symptoms resulting therefrom, point strongly to alteration in the secretory epithelia of the tubular system, which changes, since not marked microscopically, must, perhaps, be rather of a molecular or bio-chemical nature. Present indications support the view of Luff[6] that a long-continued so-called functional affection of the epithelium of the convoluted tubules may antedate those cases of gout in which structural alteration in the kidney is not evident. This change, although molecular, may be none the less evident in its effect; a similar involvement of that part of the tubular system concerned in the elimination of these toxins, the undue retention of which induces a uræmic blood state, may be the chief pathological condition underlying the symptoms in those cases of nephritis in which intoxication is evident without marked apparent implication of the secretory system of the kidney to account for the symptoms. So little is known of the intimate nature of the toxins inducing so-called uræmia, whether they are always similar poisons and not foreign to the organism in health, such as bodies allied to the xanthin group, the toxicity of

[5] Many of the examinations in the past year in this case, both chemical and microscopic, were made for me by Dr. A. A. Ghriskey, to whom I am much indebted. It is needless here to describe the technique employed in the examinations for albumin in these cases. This is given in detail in my previous papers.

Digitized by Google

which is little if at all apparent without damaged kidneys, because of its free elimination, or whether they be substances unknown normally, which are generated either in the kidney or on the other side of it, in the organism, from waste products in themselves harmless, is at present conjectural. Our knowledge is, indeed, but conjecture as to the mode of origin and manner of excretion of such waste products as urea and uric acid and the allied xanthin derivatives. At present the trend of evidence is in favour of the view that except in conditions of hyperleucocytosis uric acid is formed only in the kidney, and, perhaps, by the epithelium of the convoluted tubules, which is concerned, too, in its subsequent excretion. It is held on good evidence that uric acid excretion is commonly deficient in gout, and that its accumulation in the blood, through imperfect elimination, is one of the causes of an outbreak of the malady. This is the view of Garrod, of William Roberts, of Levison,[7] and others. This faulty elimination is now regarded as probably due in nearly all cases to preceding disease of that portion of the kidney concerned in the excretion of uric acid. Such changes, as has been said, are looked upon in certain instances as being at first merely functional. As concerns intimate knowledge of urea formation and its mode of excretion we are still somewhat in the dark. Apparently its seat of formation is the liver and its source the proteids of the food. Some experiments I recently began (the details of which, as they are yet but in their incipiency, I shall not here give) as to the influence of urea ingestion on urea excretion in the subjects of chronic nephritis tend to show that diminished urea excretion in at least some cases of nephritis, and those, too, with frankly damaged kidneys, is not so much the result of urea retention as it is of deficient formation. If subsequent experiments support these results the situation will still be more perplexing. This suggests either that the long overtaxed, crippled kidney has gradually called a halt on urea formation in the liver, although the nitrogenous intake remained high, and the digestive condition for its transformation into soluble products, the supposed antecedents of urea, remains good, or that the kidney itself is at least somewhat concerned in urea formation, and that its seat of formation here, as with uric acid, may not also be the seat of its excretion.

The purposes of this paper do not permit of a discussion of these problems, which are mentioned here merely to point out our lack of knowledge of many points in the pathology of chronic nephritis. The most important practical point in the matter is the recognition of such cases as I have described, occurring as they do with an albumin-free urine, a single specimen of which as regards absence of albumin and as regards colour and specific gravity might be viewed as normal. I need not here again call attention to the necessity for searching microscopical examination of the urine for morphological kidney elements, which steadily evident cannot but indicate structural change. The constant presence of casts can have but one meaning when associated with imperfect elimination of urinary solids, such as urea, and with the occurrence of such symptoms arising from inadequate kidneys, such as headache, vertigo, debility, and persistent presence of raised blood pressure.

Philadelphia.

[7] Levison believes that renal diseases always antedate gout, and that such disease has its seat in the epithelium of the convoluted tubules. He holds that this portion of the kidney is the starting place of granular kidney, from which such interstitial changes as occur are secondary. Greenfield regards the glomeruli as the seat of the incidence of granular kidney, from which the degeneration in the epithelium of the convoluted tubules and the connective-tissue changes are secondary.

Schirmer, of Basle, has been appointed to the newly-established Professorship of Odontology. Dr. A. Dubler, Extraordinary Professor of Pathological Anatomy and Bacteriology, has been obliged, owing to the weak state of his health, to retire.—*Vienna:* Dr. Hugo Wintersteiner has been recognised as *privat-docent* in Ophthalmology.

CURATIVE TREATMENT OF VAGINAL HYDROCELE BY THE INJECTION OF SOLUTION OF CORROSIVE SUBLIMATE.

BY JAMES MILLER, L.S.A. LOND., L.F.P.S. GLASG.,
VISITING SURGEON TO THE SOUTH LAMBETH, CLAPHAM, STOCKWELL, AND NORTH BRIXTON DISPENSARY.

"THE improvements in surgery within the present century are undoubtedly numerous and of considerable importance; but as the art is still progressive it seems the duty of every practitioner to memorise whatever by experience he finds useful, and to endeavour to increase a fund of knowledge which successive observations have gradually accumulated." So, in 1796, wrote James Earle, senior surgeon to St. Bartholomew's Hospital, and it is just as true in 1897 as it was over a century ago. It is this "duty of every practitioner to memorise what he finds useful" that must be my excuse for again bringing forward a subject which, though simple in itself, has even of late given rise to a fair amount of controversy—viz., the treatment of hydrocele of the tunica vaginalis. In 1886 I recorded in THE LANCET[1] four cases which I had treated by the injection of solution of corrosive sublimate. This treatment gives no more inconvenience to the patient than the simple tapping, as after drawing off the fluid the solution is injected into the sac of the tunica vaginalis before the cannula is withdrawn. I have since had the opportunity of treating four other cases with complete success, and to gather notes of nine cases so treated by other surgeons since the publication of my paper in 1886.

CASE 5.—The patient, a man, aged forty years, was sent to me for operation by Mr. Weston. He had been troubled with a hydrocele on the right side for some months. On Aug. 4th, 1888, having withdrawn the hydrocele fluid, I injected fifteen minims of the one-grain-to-the-ounce solution = $\frac{1}{32}$ grain of the salt. He was highly nervous and fainted with the tapping, but he soon rallied. I saw him again on Nov. 10th, 1888. The hydrocele of the tunica vaginalis had all gone, and the testicle was felt in its normal position. He was quite well, and had only stayed away from work one day. There was, however, a small fluctuating swelling between the external ring and the testicle on the right side, which moved a little up and down, but did not disappear in any position. There was no pain, and the swelling had come on gradually as the former one had gone. As it was not large it was left alone for a time. On Aug. 1st, 1892, he came to me saying that the small swelling had grown larger and was beginning to give him trouble. On examination there was found a globular tumour, tense and fluctuating, evidently a hydrocele of the cord. I tapped it, and drew off three ounces of fluid, and injected as for the hydrocele of the tunica vaginalis. On the 4th there was a recurrence of the swelling, but no pain, and the patient had not been prevented from working. I saw him again on the 16th, and the swelling had all gone.

CASE 6.—The patient, a man, aged forty-six years, came to me on Dec. 20th, 1889. About fifteen years previously he hurt his testicles and was laid up for a few days. Soon afterwards he noticed that the testicle on the right side was larger than it used to be, but there was no pain. It thus remained until about five weeks before, when it began to increase rapidly. He was tapped, and eighteen ounces of hydrocele fluid were taken away, and fifteen minims of solution were injected. I saw him on the 23rd, and there was a good amount of re-accumulation, but the patient said it was smaller then than it was the day before. I saw him again at the end of three weeks, when the fluid had all been reabsorbed and the scrotum was quite natural. He did not lose any time from his work, and at the beginning of 1896, when I last heard of him, he was quite well.

CASE 7.—On March 1st, 1890, a man, aged forty years, came to me. Five years before he had noticed a swelling of the right testicle, which was tapped after six months, and seven ounces of fluid came away. He was tapped again nine months later, and the same amount of fluid came away. The right side again swelled, but not so much. About twelve

[1] THE LANCET, Dec. 4th, 1886, p. 1072.

Digitized by Google

months after the second tapping the left side of the scrotum began to swell, and had gone on increasing until the present time. There was now a large hydrocele on the left side, and he complained of a dragging pain in the groins for the last three weeks. He was tapped and ten ounces of blood-stained fluid of specific gravity 1025 were removed, and the microscope showed blood corpuscle. He was injected with 20 minims of the solution. On the 5th the scrotum was swollen and of a dull red colour. The patient said that on the 2nd the scrotum was nearly as large as before it was tapped. It had become smaller since, the fluid being re-absorbed. On the 8th it was much smaller. By April 19th the fluid had re-accumulated; the swelling was tapped again, and eight ounces of fluid were removed and 15 minims of the solution were injected. On the 22nd the patient was going on all right, and from this date the swelling gradually disappeared. At the present time there is no sign of it.

CASE 8.—The child of a neighbouring medical man, aged three months, in November, 1883, developed a hydrocele of the tunica vaginalis. Evaporating lotions were tried, but there was no result. The fluid was therefore drawn off and 10 minims of the solution were injected. In a few days the swelling had all disappeared, and there has been no return of it.

Remarks.—In addition to these eight cases of my own I have been able to gather the following. In 1887 Dr. Wintle, of Forest-hill, S.E., treated a case with injection of solution of corrosive sublimate with perfect success. This case, he states, "had previously resisted every sort of treatment." In 1889 Mr. Hind, of St. Heliers, Jersey, mentions four cases which he had treated with injection of solution of corrosive sublimate, all of which were cured.[2] In the same year Dr. Barnard, of Alderney, mentions three cases treated by the same method, and in none of which was there any return of the hydrocele.[3] In October, 1895, Mr. Swinford Edwards, at the general meeting of the Medical Society of London, during a discussion on the Radical Cure of Hydrocele by Excision of the Sac, related a case of a medical man who had cured himself of a hydrocele by the injection of solution of corrosive sublimate, one grain to the ounce. In November, 1895, Mr. N. W. Holmes records a case[4] of a man, sixty-eight years of age, whom he treated by the injection of corrosive sublimate, and there was no return of the hydrocele. A second case was sent to me by Mr. Weston and was treated in the usual way, but he left England for Canada three days later, and as I have no after-knowledge of the case I do not include it in this review.

I should also say that in Case No. 2 recorded in my former paper there was a return in 1889. It was treated as before, and the surgeon who had the patient under treatment at the beginning of last year informs me that there was no sign of any hydrocele then.

We have here, therefore, the history of seventeen cases, all cured by the use of this injection, only two of which had to be operated on a second time. In a paper by Mr. Lockwood,[5] giving a report for ten years of cases operated upon at St. Bartholomew's Hospital, he says: "Seventy-four patients were treated by injection; in five of these the results were doubtful and were not cured when last seen. In twenty-four the injection had undoubtedly failed. The injections used were iodine, black wash, and carbolic acid. Thus the chances of relapse after an attempt at cure by injection are very considerable, rather over 32 per cent., according to the statistics of St. Bartholomew's Hospital. Evidently the operation is not one to be recommended with confidence." This is certainly not very encouraging for treatment by injection, but I should like to see a further trial given to injection by substituting the solution of corrosive sublimate for the various other medicaments which have been used. The most convenient strength for the solution is one grain to the ounce, of which, after the withdrawal of the hydrocele fluid, 15 minims (= $\frac{1}{33}$ grain of the salt) are to be injected into the tunica vaginalis and left in. There is very seldom any pain, and if there is any it is easily allayed by the application to the scrotum of a little belladonna liniment. In the course of two days there is a re-accumulation of fluid (which may somewhat disappoint the patient), but on the third day this usually begins to be reabsorbed, and the whole thing subsides in the next few days. If treated in this way there is no need for the patient to discontinue his employment. If more of the salt is used it usually produces an excessive amount of inflammation in the scrotum and a corresponding amount of systemic disturbance. In the case reported by Mr. Holmes, referred to above, there was a good deal of inflammation and systemic disturbance, which necessitated the patient keeping his bed for three days, but this I should attribute to the amount of the salt used, viz.: $\frac{1}{4}$ grain instead of $\frac{1}{33}$ grain. The same thing occurred in Dr. Wintle's case, and also in Case 7 as above. As to the cases that are suitable for the treatment, I can only say that it has answered perfectly in cases from the age of three months to sixty-eight years, and as well for the old-standing hydrocele with thickened walls as for the newly acquired. If by the minimum amount of palliative treatment we can obtain the maximum result of curative treatment there is certainly a distinct gain. That some cases will fail I make no doubt, but that the percentage of failures will be very much reduced I feel as fully assured.

A CASE OF LEAD-POISONING COMPLICATED BY ULCERATIVE COLITIS.

BY H. W. CARSON, M.R.C.S. ENG., L.R.C.P. LOND.,
RESIDENT MEDICAL OFFICER, TOTTENHAM HOSPITAL.

I HAVE thought this case worthy of publication on account of the extreme rarity of the complication.

A man, aged thirty-seven years, was admitted to the Tottenham Hospital on Aug. 14th, 1896, with the following history. He was a painter, but had been out of work, with the exception of the last few days, for some time. About seven years before he had suffered from an attack of lead colic, but with that exception he had been, apart from occasional attacks of "gout," a healthy man. He came to Tottenham Hospital complaining of severe abdominal pain and constipation, which began on Aug. 11th, three days previously. There was much sickness on the 12th, and the pain continued with exacerbations till the day he was admitted. He had then walked up to the hospital, a distance of four miles, accompanied by a friend, and he arrived in a very collapsed state. There had been no action of the bowels since the 10th.

Condition on admission. — The patient was a poorly nourished man, very anæmic, with a sallow complexion. He seemed to be in a collapsed condition; the pupils were equal, contracted, and with slight reaction to light. The teeth were much decayed; the gums of the lower incisors and canines had retracted, presenting a marked blue line, and there was a brown fur on the dorsum of the tongue. The grasp of the hands was good and equal and there were no signs of extensor paralysis. The knee-jerks were present. The pulse (after recovery from the collapse) was 100 and of good tension, and the artery was not rigid. The heart was natural. The abdomen was slightly distended; it moved freely on respiration. General pain, not relieved by pressure, was present, but no tender spot was noted. The urine was of specific gravity 1020, of acid reaction, and with a slight cloud of albumin.

Treatment.—At first a saline purge was administered with iodide of potassium, and on the same night (Aug. 14th) the bowels were opened three times, the motion on the third occasion consisting chiefly of blood. The pain was not relieved by the evacuations. On the 15th the patient had eight actions, consisting of slime with shreds of mucous membrane and a little blood. The pain in the abdomen continued to be severe and there was some tenderness over the ascending colon. Belladonna fomentations were applied, but were discontinued as pressure seemed to increase the pain. The hæmorrhage and diarrhœa continued throughout the 16th, the abdominal pain had ceased, but tenderness was still present over the ascending colon. During the day he passed only nine ounces of urine, which had the same characters as before. The hæmorrhage then ceased, with the exception of two small clots on the 20th, but the diarrhœa (from six to seven actions a day, each action containing some mucous shreds) continued till the evening of the 26th, when he had a large hæmorrhage and, becoming collapsed, died

Digitized by Google

at noon on the 27th. During the six days preceding his decease the patient's condition became gradually weaker and he was at times delirious, but usually comatose. He could always be roused from the coma by asking questions, and would answer sensibly, then almost at once relapsing into his former condition. Whilst delirious he would mutter to himself, and occasionally groan and cry out, but he never complained of any localised pain. Throughout the illness the temperature only rose on three occasions as high as 99·6° F. and was never below 98°, except on admission, when he was collapsed, and at the time of, and following, the final hæmorrhage, when it fell to 97°.

Necropsy.—The lungs were emphysematous and somewhat congested. The heart and stomach were natural. The small intestines contained a quantity of very offensive fæcal matter. The lower end of the ileum was much congested and contained shallow ulcerated patches not confined to the solitary follicles. The whole of the large intestine presented the characters of an ulcerative colitis. The mucous membrane, which was dark-coloured, was stripped off the bowel in places and hung in shreds. There were no signs of perforation, but the ascending colon was firmly adherent to the capsule of the right kidney. There was no general peritonitis. The liver was small and cirrhotic. The spleen was small and densely hard. The capsule of the kidneys peeled readily and there were no signs of cirrhosis.

Remarks.—The rarity of the complication is shown by the omission of all mention of it in the great majority of text-books. The first account I find is that given by Tanquerel des Planches,[1] in which he says: "Lead colic may be concomitant not only with other lead diseases, but with maladies arising from causes unconnected with lead preparations. These complications exist independent of colic; they are not in the least influenced by the treatment, yet they modify the character of the colic." The complications mentioned are gastritis, enteritis, peritonitis, and dysentery. In a short paragraph in which this writer discusses enteritis as a complication he draws attention[2] to "the swollen abdomen" and to the facts that "pain tends to generalise itself, but is often more acute in parts, constant, increased by pressure, becoming more severe at times" and that "evacuations give no relief." All these points are well brought out in the case above described, and it will be noticed that colic and constipation, two of the most constant symptoms of lead poisoning, were to a great extent obscured by the colitis to which is attributable the localised pain and diarrhœa. Under the head of "Lead Poisoning" Osler[3] mentions a case with similar features to the present one, which came under his care in the Philadelphia Hospital. The patient "had vomiting, constipation at first, afterwards severe diarrhœa and melæna, with distension and tenderness of the abdomen. There were albumin and tube-casts in the urine. The temperature was usually subnormal. Death occurred at the end of the second week. There was found the most intense entero-colitis, with hæmorrhages and exudation. These acute forms develop more frequently in persons recently exposed." With regard to the causation of the colitis, in spite of Tanquerel's statement, above referred to, that the malady arises from causes unconnected with lead preparations, it seems possible that, in some cases at least, lead may be the direct cause. Dr. Oliver[4] says: "It seems to me as if lead first irritated the sympathetic and intestinal ganglia; this is followed by spasm of portions of intestines and arteries." And again[5]: "How far a degree of heightened arterial tension, associated from time to time with the minor attacks of pain in the abdomen and the constipation which so usually accompanies it, aid in developing anæmia or cachexia by causing malnutrition through impeded flow of blood it is impossible to say." Arguing on these lines, then, is it not possible to consider the colitis due to malnutrition of the mucous membrane of the colon, caused by impeded flow of blood through the vessels to the affected parts. Another possible explanation is that lead may, in some cases, have an action on the trophic centres of the cord governing this area, for such centres must assuredly exist. In this connexion Dr. Oliver mentions[6] Oeller's case of lead-palsy where hyperæmia and atrophy of the ganglion cells in the anterior cornua of the grey matter of the cord were demonstrated microscopically.

My thanks are due to Dr. Overend, under whose care the patient was admitted, for permission to publish these notes.

VITALITY.[1]

BY LIONEL S. BEALE, M.B., F.R.C.P. LOND., F.R.S.,
EMERITUS PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE IN KING'S COLLEGE, LONDON, AND CONSULTING PHYSICIAN TO THE HOSPITAL; GOVERNMENT MEDICAL REFEREE FOR ENGLAND.

VIII.—THE INTERSTITIAL CIRCULATION IN ALL LIVING THINGS (*continued*).

THE constantly flowing currents necessary for the life and increase of the living matter, and instrumental in preserving the integrity and activity of the formed material of the tissues and organs of living forms, originate in, and are maintained by, the particles of living matter (bioplasm) which are seen to be embedded in enormous numbers in all parts of every tissue.

To form a correct idea of the actual arrangement of the particles of the living matter, and to gain a knowledge of the important part they play in connexion with the interstitial circulation, it is necessary to examine very thin sections of the tissue; but in this inquiry it is almost impossible in the case of many very soft textures to obtain the requisite degree of thinness without seriously disturbing the natural relations of the parts. One may often get more accurate information from a careful examination of a naturally thin portion of the tissue, such as is sometimes to be found here and there as an extension from the organ or tissue under investigation. In this the tissue elements and bioplasts, with the capillaries and nerves, will be seen in their natural position, not forming more than a single layer. Such specimens may be made still thinner by careful pressure if the structure has been allowed to soak for some time in glycerine or syrup. Tissues preserved in such media can be examined with very high magnifying powers, and will retain their characters for thirty years or more if carefully mounted. The details of preparation by this method were described in "How to Work with the Microscope," and will also be found in papers in the Transactions of the Royal Microscopical Society many years ago. Dilute solutions of glycerine and syrup in which the fresh specimen is immersed, if kept for some time at a temperature of 100° F., will undergo considerable but very gradual concentration without the relation of the tissue elements to one another being in the slightest degree disturbed. At the same time great transparency is obtained, and very delicate structural points can be clearly demonstrated by the aid of powers magnifying 700 diameters and upwards.

Every organism, as I think I have distinctly proved, every organ, every structure forming part of a living thing, from the smallest to the most colossal forms, from the most ancient to the most recent, consists of matter in two distinct states or conditions—the one *living*, the other *formed*. All the formed material or tissue, however firm or dense and hard and dry, was once in the state of soft, moist bioplasm, living or germinal matter. During this state the arrangements upon which its tissue-characters depend were made. The ultimate form, properties, and composition of all formed material depend upon the vital changes which occurred in the bioplasm before the formed material was produced. So delicate and transparent are some even fully formed tissues that their actual arrangement can hardly be demonstrated with the highest powers. Their structural elements would collapse but for the support they receive from the fluid that lies in the spaces between the delicate fibres. In some organisms even contractile muscular tissue and nerve fibres are transparent and are supported by the fluid medium—the interstitial fluid which during life is always undergoing change—around them. Not only are nutrient matters dissolved in the interstitial fluid, but certain substances formed during the action of the living matter and others from the

[1] Nos. I., II., III., IV., V., VI., and VII. were published in THE LANCET of Feb. 22nd, April 11th, June 13th, Aug. 29th, Oct. 17th, 1896, Jan. 23rd, and July 31st, 1897, respectively.

Digitized by Google

disintegration of the formed material become mixed with the nutrient matters brought within the sphere of action of the bioplasm for its nutrition. These two classes of substances, the one about to live, the other resulting from changes during life and from the disintegration of that which has lived, are very intimately mixed together in water in which both are dissolved.

The multitudes of the living particles (bioplasts) which exist in all tissues and organs of every living thing, although having very different powers and forming very different matters structurally and chemically, are in all cases the direct descendants of the original living particle of germinal matter or bioplasm which gave rise to each particular individual organism. Every one and every part of one is dependent for nutrition, growth, multiplication, and action—for life itself—upon the free supply of interstitial fluid. Sometimes the living matter is not in distinct, separate, and detached particles, but the little masses are stellate in form and the rays are continuous, so that we have a network of bioplasm extending through the tissues. At an early period of life when a sufficient number of detached or continuous particles of living matter have been produced, formed material begins to appear around and between. After a time the living matter is embedded in this formed material, which has been produced by the bioplasm, and is dependent for the preservation of its integrity upon the free and continual circulation of the interstitial fluid. The more recently developed, the younger bioplasts of a portion of tissue, are larger than the older ones and have a thinner layer of formed material around them. In multitudes of the mature lowest forms of life, and at the earliest period of individual life in all, there may be but a single mass of living matter, generally less, and sometimes very much less, than one-thousandth of an inch in diameter. In many organisms the bioplasm particles are far more minute than this, but in every one and in the formed material around each there is interstitial circulation.

In no tissues that are active are these little particles separated from one another by distances much greater than three or four times their length or diameter, and the intervening formed material is everywhere the seat of interstitial circulation. In parts of many nerve centres and in secreting and other organs where active changes are constant the particles of bioplasm are near together, and in certain structures that are constantly being formed through life even in the adult they almost touch one another. At a very early period of development in all living things, present and past, the whole organism consists of these little bioplasts or particles of living matter so close together that only a thin layer of transparent semi-fluid matter intervenes and enables us to define the several particles. In many situations the bioplasts are in the proportion of millions to a cubic inch of tissue. In the deep layers of the cuticle, on the surface of certain mucous membranes, and in the superficial layer of the cerebral convolutions just beneath the pia mater, they are very close to one another throughout life in health, and in the last situation the interstitial circulation is very active, and special arrangements exist by which a free and rapid interchange of fluid is ensured. Each of the millions upon millions of bioplasts in a moderate-sized organism possesses active vital power and takes part in the interstitial circulation as long as life lasts; each, in fact, causes and is dependent for its life upon the interstitial circulation. Each draws to itself some of the surrounding fluid, selecting and appropriating certain of its constituents, and also yields up to the fluid certain matters that are eventually removed from the organism.

Everything taken up by living matter must be in solution in water, and before substances resulting from disintegration which takes place in every part of living organisms can be removed they must also be dissolved. Water is the principal constituent of all nutrient substances, and is more than the mere vehicle for carrying the solids to their destination. It is always present in large proportion where active growth is proceeding All active tissues and most passive ones contain it in large proportion, and in rapid changes much is required. Even tissues that seem to be dry contain some water. Fluid containing various matters is found pervading the tissues, not only passing through the interstices, but moistening every part of the anatomical elements, and, as I have before remarked, every form of bioplasm invariably contains much water. It is probable that there is not a molecule—not an atom of the matter of which a living particle is constituted—that is not free to move in all directions amongst its neighbours and coalesce with them by reason of the fluid medium which is essential, if, indeed, water is not actually combined with some of the constituents of living matter.

The proportion of water to the dissolved constituents is largest at an early period of existence when the changes in living matter are most active. The interstitial fluid is always changing in composition, always receiving certain constituents, always giving up some to be converted into living matter, and some to be changed in order that they may be eliminated altogether. In all cases, however, the proportion of water to the solids in the interstitial fluid is so considerable that it usually amounts to more than 95 per cent. A very high state of dilution seems to be universal in the case of solutions taking part in vital phenomena. The smallest quantity of water that is absolutely necessary has not been determined, but it is certain that a very moderate degree of concentration is detrimental, and may cause serious derangement both in the living matter and in the formed material. Solid matters may be deposited in the substance of the tissues, the action of which may be seriously impaired, and the death of the living matter would probably occur before a considerable degree of concentration could be reached.

Wherever the atoms of living matter undergo those wonderful alterations in position and relation to one another which invariably occur preparatory to tissue formation of any kind, and to the production of substances of definite chemical composition and properties, the interstitial circulation is most active; but when tissue and definite substances have been formed, and vital changes are carried on but slowly, locally or generally, as in old age, the interstitial fluid is small in amount, and its movement comparatively slow. In cases where part or the whole of a tissue has become hard and dry, or almost dry, as in the oldest portions of some bony tissues, in fully-formed dentine, enamel, and shell, in the oldest and driest parts of hair, nail, and horn, the interstitial fluid circulation will have entirely ceased and the bioplasm will have disappeared.

In all fully-formed, mature, complex organisms the food substances and water required for growth, nutrition and action are, as we well know, introduced in one part of the body, modified in composition, and then distributed to parts at varying distances from the seat of introduction by special tubes or vessels with very thin walls, which have been formed for the purpose at an early period of development. In some cases the network of minute tubes extends through every part of the entire organism wherever living matter exists. In others the new matter passes into minute vessels soon after it has been introduced, and from these into larger ones, and at last into a single trunk, which perhaps has propelling power or is connected with a special propelling apparatus or heart. The mixed fluid at length reaches other networks of minute vessels, by the thin walls of which a part is filtered into the tissue spaces.[2] This is the interstitial fluid, which is at once brought very near to the bioplasts of the adjacent tissues, by the vital action of which it is caused to be drawn through the layer of formed material around and introduced into the very substance of the living matter. In this way the bioplasm of every one of the millions of elementary parts in every portion of the body of the most complex organisms is freely and regularly supplied with the dilute solution, which contains everything required for nutrition, growth, and the production of formed material and for the production of chemical substances of highly complex composition for special purposes or for elimination.

The weak solution in water from which the living matter obtains all the substances it requires for its life and for conversion into new living matter is caused to flow towards the bioplasm by the vital movements of the bioplasm itself. In this way each individual particle of bioplasm of the most

[2] It is not perfectly correct to say "filtered," for the interstitial fluid is not merely a dilute solution of certain substances which has passed through passive membrane. The so-called nuclei (bioplasts) of the capillary walls take up a solution from the blood, select and appropriate certain suitable matters, convert these into bioplasm, a portion of which soon undergoes change, and a weak solution of the resulting substances becomes the interstitial fluid. This process, in which bioplasm takes up certain substances and converts some into new living matter, a portion of which at the same time becomes resolved into lifeless compounds, really occurs in every particle of living matter through nature, and so far no other way has been discovered in which the various structural and chemical substances characteristic of the various living organisms, their tissues and organs, can be produced in anything that lives.

Digitized by Google

colossal organisms is as well supplied with what it requires if it is to live and perform its vital acts as the minute individual particle free to move, to grow, and to multiply in a medium laden with the substances upon which it lives dissolved in the proportion of water which suits it.

It will be found that the same principle holds with regard to the vital actions of living things in every department of nature—every particle of living matter being dependent for its life upon an interstitial circulation which is established and sustained by itself, which begins with its life and ceases at its death. In every particle of living matter, then, we have a laboratory without apparatus and without any visible chemist, where analytical and synthetical operations are always being conducted in the most perfect manner. Movements and work proceed without any mechanical appliances and in the absence of any tangible designer, constructor, regulator, governor, or conductor. Here atoms are moved about in all directions, and may be placed above one another notwithstanding the influence of gravitation. Transformation of energy is effected in this clear, colourless, structureless substance, consisting largely of water; and movement, heat, light, electricity, and possibly other modes of motion may be evolved. Moreover, this clear, soft, structureless, living matter is capable of endless multiplication. It also differs from matter in every other known state in that it possesses powers unknown elsewhere, which have been derived from pre-existing living matter and are capable of being transmitted to particles of matter which do not yet live, and this without any loss. These wonderful vital powers, according to Lord Kelvin's most recent computation, have been passing from living to lifeless particles for about 20,000,000 years. If this be so, we may be sure that colourless, structureless, living matter, with its interstitial circulation, has existed for the same period, and that the universal vital characteristics have never ceased or been dormant for a single moment.

(To be continued.)

PUERPERAL ALBUMINURIA AND THE ACTION OF SULPHATE OF QUININE ON THE GRAVID UTERUS.

BY R. C. BENNETT, M.B., C.M. EDIN.,
GOVERNMENT MEDICAL OFFICER, TRINIDAD.

I SUBMIT the following cases with the hope that they may be of some interest.

CASE 1.—A primipara, aged twenty-two years, had been pregnant about eight months, and had suffered from œdema of the extremities for one month. This was the short history I obtained at midnight on March 13th, when I was for the first time consulted owing to the sudden onset of severe and frequent convulsive attacks. Half-drachm doses of bromide of potassium somewhat relieved these attacks. On the following morning the patient lay on her back in a stupid half-conscious condition, taking no notice of anything and being unable to answer questions. The tongue was lacerated. There was marked œdema of the extremities, the face, the labia, &c. The abdomen was enlarged, due to the advanced stage of pregnancy. There was an entire absence of any indications of commencing labour. The urine was scanty, pale in colour, and contained, roughly estimated, 20 per cent. of albumin. The bowels were constipated. There was no history of recent attacks of intermittent malarial fever. Compound powder of jalap with elaterium was ordered, also a diuretic mixture and milk and soda-water diet. No quinine was given. This briefly was the case, and the prognosis was not favourable. The marked absence of any indications of approaching labour and the prospect of having to induce it added to the seriousness of the case. On the following day there was a little improvement: the patient answered questions; there was no recurrence of the fits; the urine was less scanty, and the bowels were freely purged, but the œdema was distressing. On the next day there was some further improvement; the œdema was slightly less, but that of the labia had become painful owing to the appearance of sloughs. There were no symptoms of recurrence of convulsions and there was entire absence of any indications of labour. In spite of the slight improvement the case was regarded with anxiety. I leave this case at this stage to pass on to the next.

CASE 2.—On the day after I had seen Case 1 I was called to attend a primipara, aged twenty-four years, in about the eighth month of pregnancy. There was enormous œdema of the upper and lower extremities, the labia, the face, &c. The patient was intensely anæmic, with hurried action of the heart and hæmic murmurs and some dyspnœa. The œdema was of a recent and acute character. The urine was scanty and pale and charged with albumin. There had been no indications of convulsions. Mentally the patient was clear and intelligent. There were no signs of labour. She was, in addition, suffering from intermittent attacks of malarial fever. Treatment on general principles was prescribed, and five-grain powders of sulphate of quinine were given three times daily owing to her attacks of fever. Within forty-eight hours of taking the quinine she was delivered of a still-born child—a desirable result considering her general condition.

To return to Case 1. I ordered and issued six powders of sulphate of quinine of ten grains each, one to be given every fourth hour. I did so with the object of bringing about labour and to test the action of quinine in this direction. I was agreeably surprised at its action. Before the sixth powder was given labour pains had set in, and when I saw the patient she was in the second stage with a normal presentation. In due time she was delivered of a still-born child, large and well developed. The further clinical progress of these cases does not come within the scope of this paper. They both did well.

Remarks.—That quinine can and may induce uterine contractions and thus bring about premature labour or abortion I think there are grounds for believing. This I have before now noted, and it is also the experience of some practitioners with whom I have had opportunities of discussing the subject. I think Case 1 points to this. In treating pregnant women (the subjects of malarial fever) with quinine it is proper always to mention the possibility of abortion or premature labour (more frequently the former) taking place, and to diminish the possibility of such an occurrence one has to administer, and that cautiously, only small doses of this drug. Whether quinine acts directly on the gravid uterus or indirectly through the nerve centres is, perhaps, of no immediate importance, though information on this point would be acceptable. In the available literature on cinchona and its compounds little is said as regards the action of quinine on the uterus. Ringer's "Therapeutics" has the following sentences:—"Quinia is sometimes useful in the vomiting of pregnancy." "American writers believe that quinia strengthens the contractions of the womb during delivery and some use it in preference to ergot." "Other writers deny this action to quinia ..... quinia does not induce premature labour, though some writers have asserted the contrary."

It must be admitted that many women when pregnant take quinine with no evil results whatever. Considering that this drug is largely used in the colonies further information of its action in the direction here indicated would be interesting and valuable.

Trinidad, West Indies.

THE RELATIVE HEIGHTS AND WEIGHTS OF BENGAL PRISONERS.

BY W. J. BUCHANAN, M.B., DIPL. STATE MED. DUB.,
SURGEON-CAPTAIN, INDIAN MEDICAL SERVICE; SUPERINTENDENT, CENTRAL GAOL, BHAGALPUR.

IN THE LANCET of Aug. 24th, 1895 (p. 476), I published a table giving the relative heights and weights of Bengal prisoners. I have since collected a large number of weights and measurements—viz., 28,863—and the result has been to confirm almost absolutely the accuracy of the formula I then published. This formula runs as follows:—"Taking 100 lb. as a normal average weight for a man of 5 ft. add 3 lb. for each inch above that weight—e.g., 5 ft. 3 in. = 109 lb." That this formula gives as accurate an average height as can be expected is also shown, I think, by the fact that the results of examining 5000, 8000, 20,000, and the above total practically correspond, and the

Digitized by Google

results of a collection of some 7800 cases in the other large gaols in Bengal published in the Administration Report for 1896 are practically identical with the above formula. I have purposely avoided parts of an inch. Mr. Havelock Ellis[1] has shown this to be useless. I must note that these figures have all been taken from prisoners of the peasant class, chiefly from the Behar portion of the Province of Bengal, and are confined to adult men of the ages of from twenty-five to forty years. They do not apply to hill men, Burmese, aboriginal tribes, or to the tall, well-made Rajputs, but are representative of the average Behar and Bengal peasant.

Height.	Weight.	Number of observations.	Percentage.
5 ft.	100 lb.	1863	6·5
5 „ 1 in.	102 „	2069	7·2
5 „ 2 „	106 „	5226	18·0
5 „ 3 „	109 „	5787	20·0
5 „ 4 „	112 „	6107	21·3
5 „ 5 „	115 „	3040	10·0
5 „ 6 „	118 „	2498	8·7
5 „ 7 „	122 „	1389	4·8
5 „ 8 „	125 „	623	2·1
5 „ 9 „	129 „	220	0·7
5 ft. 10 in. to 6 ft.	—	51	0·1

A glance at the second column in the above table will show how closely the weights for height correspond with my formula given above. It will also be seen that one inch in height practically means 3 lb. increase in weight. Lombroso's rule for Italians, beginning with 5 ft. = 110 lb., gives an increase of about 5 lb. per inch for his countrymen; Allen's table of heights and weights for Englishmen gives also about 5 lb. per inch above 5 ft.; that given by Liharzik varies from 3 lb. to 7 lb. These are all the observations of this kind I can lay my hands upon at present. The above table also shows that, taking the Bengal prison population, which fairly represents the peasant classes generally, the vast majority of them are of short stature. Taking, with Mr. Havelock Ellis, heights between 5 ft. 4 in. and 5 ft. 9 in. to be medium, below that short, and above it tall (these of course are European ideas) we find that from an European point of view 51 per cent. would be classed as short, an almost equal number as medium, and almost none as tall. for out of 28 863 men measured I could only collect 51 (0·1 per cent.) of 5 ft. 10 in. and above. I have frequently had prisoners of this height, but they were generally Rajputs, or men of better social position than the average prisoner. I have also found that the average weight of this large number of men was 109 lb. In calculating relative diet scales[2] I took 110 lb. as the average, which is now shown to be practically correct. T. Lewis, F.R.S., put the average weight of the Bengali as 105 lb. The above figures are sufficiently large, I think, to draw safe conclusions from. It is not meant that these figures can be applied accurately to every individual case, but they furnish as accurate as possible a standard for healthy men of this class. Apart from their use in gaols they can be used, as has been the case during this year of famine, to compare the relative health and physique of persons of this class in unhealthy or famine years compared with normal conditions. It is much to be regretted that anthropological figures are not more frequently collected in India.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF ANEURYSM.

BY F. W. THURNAM, M.B., C.M. EDIN.

A MAN, aged fifty-four years, married, but having no children, decorator, consulted me on Feb. 15th, 1897, complaining of "rheumatic" pains at the back of the head, side of the neck, and towards the right shoulder, with slight cough There was no history of syphilis, and beyond helping to lift a heavy case of goods three months before, which had been followed by an attack of faintness, there was no history of exertion. He was said to have had gout (or rheumatism) many years back. He was ordered a mixture containing salicylate of soda and compound tincture of camphor and a liniment of turpentine and acetic acid. He was allowed to go for a week's change to Epping Forest during the first week in March. No mention had been made to me of a "sensation of internal tumour behind the collar-bone," neither had any swelling been noticed, though looked for, by himself or his wife during the three weeks of its existence. While away, on the evening of March 9th, his neck, shoulder, and upper part of the right chest were rubbed with the liniment by a relative, and though there was much pain no enlargement was seen. Next morning, however, a tumour was clearly visible above the sternal end of the right clavicle. On the 12th over the region of the right sterno-clavicular articulation was a swelling the size of a goose's egg, pulsating and indistinctly expansile, without bruit over the tumour or along the vessels; pain was felt over the site, up the neck, and down the arm, which was somewhat œdematous; the heart's apex was in the fifth space, displaced out to the nipple line; the sounds were faint; there were no murmurs; both the radial arteries were atheromatous; and there was no appreciable difference in their pulses. There were a troublesome hacking cough, some difficulty in swallowing, and alteration in the voice. My diagnosis was aneurysm of the innominate artery. A mixture containing iodide of potassium and tincture of opium was given. On the 15th the patient was seen in consultation with Dr. H. B. Carter, and, to exclude the possibility of abscess, disease of the joint or other growth, an exploratory aspiration was made with a hypodermic needle, but it showed no pus and only withdrew blood. A red blush over the swollen area, with increased fluctuation in the centre, gave the impression that the skin was much thinned. There was exophthalmos of both eyes, more particularly of the right, the pupil of which was more dilated as compared with the left. The ophthalmoscope showed the vessels of the right retina to be more distended than those on the left side. The laryngoscope showed no laryngeal paralysis. The cough was due to irritation by compression of the right recurrent laryngeal nerve. On the 31st the patient was admitted to the London Hospital, under the care of Mr. Hurry Fenwick, to whom my thanks are specially due for the summary of the notes taken during the patient's stay there of one week. "Rapidly growing innominate aneurysm; inoperative; doubled its size while in hospital." On April 7th the patient was discharged from the London Hospital, where an ice-bag had been used which was continued intermittently, as well as the iodide and opium mixture. There was no œdema of the arm at that time. There was slight delirium at night. In May the prominence and extent of the aneurysm seemed to vary; it was generally fuller at night; there were frequent convulsive twitchings of the arm and leg, more so during sleep. The appetite was fairly good, but capricious. As little fluid as possible was allowed in his diet. In June the aneurysm was increasing in size and extending to the left across the episternal notch. There were frequent attacks of sickness and diarrhœa, alternating with constipation. There was more pain in the neck and arm. The patient was confined to bed throughout. In July the position of the right clavicle had become much more pushed downwards than its fellow, and, partly owing to

Digitized by Google

more tenderness and erythema over the sac, no articulation with the sternum could be made out. In August there were increasing asphyxia, loss of power, and pain in spite of pushed doses of opium, chloral, and bromide, as well as belladonna locally. For the last three days of life there were œdema of both hands and much sweating. His florid complexion was maintained till the morning of his death, for two hours before which there were marked pallor and complete unconsciousness.

Necropsy.—The post-mortem examination was made on Aug. 12th, eleven hours after death. An examination of the chest only was allowed. The aneurysm was of the arch of the aorta, saccular, not diffuse, and there had been no rupture of it. The sac was the size of two fists and extended upwards to above the cricoid cartilage, and, having destroyed the right sterno-clavicular joint, depressed the clavicle and overlapped the right half of the sternum to below its junction with the second rib, the sternal end of the clavicle and the outer and posterior upper portion of the manubrium being completely eroded. The aneurysm commenced just internally to the origin of the innominate artery, which, beyond compression by the sac, was scarcely, if at all, implicated in it.

Remarks.—The points of interest in this case are the sudden appearance of the aneurysm, its rapid growth, and peculiar distribution. The possibility of its being aortic was not lost sight of: but certainly at the time of diagnosis and, indeed, until the extension of the enlargement to the left, two months later, all the symptoms pointed to its having an innominate origin. The one point of consolation is that no operative interference was resorted to.

New Cross, S.E.

TWO CASES OF PHTHISIS IN WHICH KOCH'S NEW TUBERCULIN WAS TRIED.

BY F. M. SANDWITH, M.D. DURH., M.R.C.P. LOND.,
PHYSICIAN TO KASR-EL-AINI HOSPITAL, CAIRO.

CASE 1.—The first patient was a German who for four years has had tubercle of both lungs. Koch's instructions were followed in all particulars, and the initial injection was $\frac{1}{500}$ milligramme, or two micro-milligrammes. The patient's temperature taken at 7 A.M. and 7 P.M. ranged before treatment from 97·8° to 99·4° F., but the injection was invariably followed by a reaction, sending the evening temperature up to 100·2° or 101°, and after three micro-milligrammes had been injected the evening thermometer showed 101·4° and 101·6. But the morning temperature never rose above 97·8°, showing that the reaction only lasted a few hours. The injections were all made at 10.30 A.M. For the first two days the expectoration notably diminished, but then increased, especially at night. After three weeks the injections had to be discontinued because of slight pleurisy and hæmoptysis. From the previous history of the patient I do not think that either of these complications were due to the tuberculin TR. The pulse and respiration rate hardly changed in spite of the temporary rise of temperature, being always 70 and 13 to 14 in the mornings and 97 and 20 to 22 in the evenings.

CASE 2.—The second patient was a Greek, also suffering from chronic tuberculous lung disease. In his case there was also a temporary rise of 1° F. after injections of two, and again later after injections of three, micro-milligrammes. In his case there was also some local reaction, as shown by the appearance of pain and some diminution of swelling in a tuberculous epididymis. His lung symptoms seemed to improve under treatment. It is of course quite likely that Koch himself would have thought these two cases unsuitable for his new discovery.

The tuberculin TR contains not the toxin but the components of the bacilli themselves, and will probably be found very useful for lupus without complications. If all lung cases react as easily as mine, the injections might be used as a method of diagnosis more delicate and less dangerous than the old tuberculin. At present one is a little shy of a remedy which is to be increased in dosage from $\frac{1}{5000}$ milligramme to 20 milligrammes—i.e., the minimum dose is 10,000 times smaller than the maximum. To become popular the new remedy must be made easy to obtain, less costly, and must be diluted in a less cumbersome way, if "the dilution is always to be prepared at the time it be used." The tuberculin itself is painless, but the glycerine in the solution causes a little stinging.

Cairo.

A CASE OF CÆSAREAN SECTION FOR CYESIS COMPLICATED BY MALIGNANT DISEASE OF THE RECTUM.

BY ALBERT J. RIDDETT, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE OBSTETRIC HOUSE PHYSICIAN, MIDDLESEX HOSPITAL.

ON Aug. 3rd, 1897, I was hastily summoned by a midwife to see a patient, aged thirty-seven years, who according to the account given me had been in labour twenty-four hours. I found the patient in a marked degree of prostration, the pulse 120 and occasionally intermittent; she had also vomited two or three times. On abdominal palpation I found the fœtus lying transversely with the cephalic extremity to the right side of the pelvis; per vaginam the posterior vaginal wall was found to be pushed forwards, and a hard irregular mass could easily be made out blocking up the pelvic outlet. The true conjugate diameter only measured two and a half inches. Per rectum about four and a half inches from the anus a hard nodular swelling was felt, which bled even on careful manipulation. Uterine contractions were frequent and strong, so I at once gave a quarter of a grain of morphia hypodermically; this was at 6 A.M. and effectually stopped the contractions. From the cachectic appearance of the patient, the evident wasting, a history of occasional diarrhœa, together with the presence of a tumour and the patient's age, I had no doubt that it was a case of malignant disease of the rectum, which had taken on a rapid growth during the later weeks of pregnancy. This was, I learnt, the sixth confinement, the five previous ones having been quite normal. I put it to the patient's friends that either craniotomy or Cæsarean section must be performed, strongly advocating the latter, inasmuch as I thought craniotomy would be dangerous, probably causing sloughing of some portion of the growth and consequently septic mischief. I saw the patient again at 9 A.M., when, as the uterine contractions were recommencing, I gave another injection of morphia (quarter of a grain), and had her prepared for operation, the patient and her friends having given me permission to perform Cæsarean section. Ether having been administered I opened the abdomen by the ordinary laparotomy incision; then my friend, Dr. Owen Williams, who kindly assisted me at the operation, firmly compressed both broad ligaments, thus effectually controlling the blood-supply to the uterus; the latter organ was quickly opened by a median longitudinal incision, sponges having been placed on either side to prevent escape of liquor amnii into the peritoneal cavity; the fœtus was extracted, and the placenta (which was on the posterior uterine wall) with the membranes expressed. There was but an insignificant quantity of blood lost. The uterus contracted well under the stimuli of pressure and hot sponges. The muscular wall of the uterus was closed by twelve deep silk sutures, which did not include the mucous membrane; superficial Lembert's sutures were next inserted, so that the peritoneal surfaces accurately approximated. The Fallopian tubes were next tied and divided. The uterus, which had been partly withdrawn from the abdominal cavity, was now replaced and the abdominal wall sutured in three layers—(*a*) the peritoneum with catgut, (*b*) the sheath of the rectus with silk, and (*c*) the skin and superficial tissue with silkworm gut.

I may say that the case resembles somewhat one Dr. Wm. Duncan had whilst I was his house physician at the Middlesex Hospital, and in the operation I have recorded I endeavoured to follow as closely as possible Dr. Duncan's methods. The patient is now practically convalescent and has had an uninterrupted recovery save slight vomiting which commenced about twelve hours after the operation; this was stopped by means of iced champagne. The child (a male) is alive and doing well.

LONDON TEMPERANCE HOSPITAL.

A CASE OF PIROGOFF'S AMPUTATION.

(Under the care of Dr. W. J. COLLINS.)

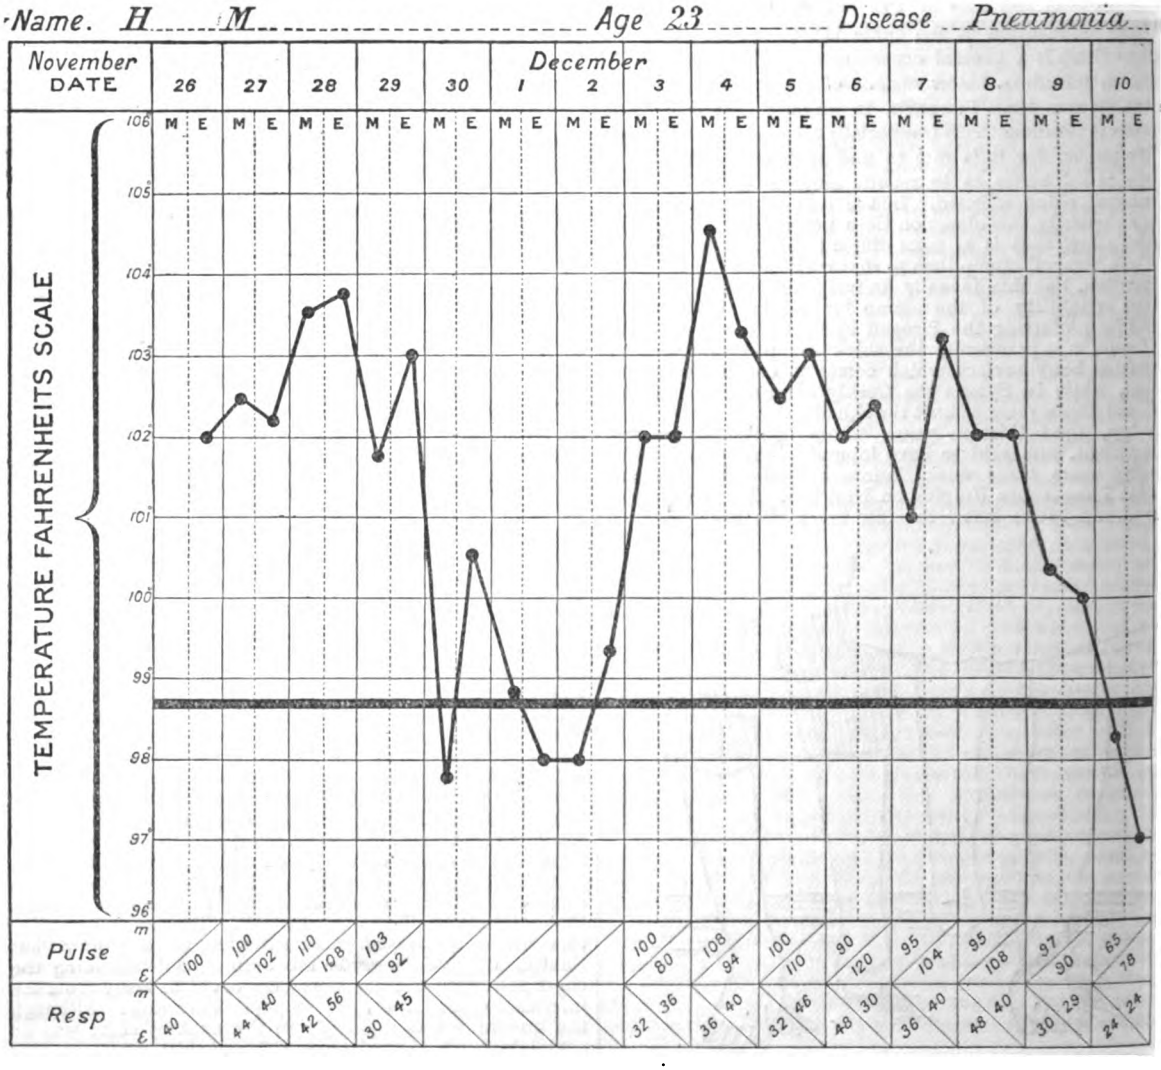
WHEN amputation at the ankle is required for disease of the foot there is a general consensus of opinion that Syme's operation affords a better chance of the complete removal of the disease than Pirogoff's, in which a portion of the os calcis is retained. This is especially the case in tuberculosis of the tarsus, for it is rare to find such extensive disease of the tarsal bones as to require amputation without the calcaneum being affected. In the case of amputation for injury obviously this objection does not apply. Instrument makers assert that it is more difficult to adapt an artificial foot to a Pirogoff stump than to that resulting from a Syme's amputation, but this is really an imaginary difficulty. The greater suitability of the stump for walking is the chief reason for preferring the Pirogoff operation to the other; in the former it is practically the thick heel pad supported by a rounded bony surface which comes in contact with the ground, while in Syme's the freshly sawn surfaces of the tibia and fibula press against the skin flap.

A boy, aged thirteen years, whose family history was unimportant, was said to have injured his right foot when jumping some three weeks before his admission to the London Temperance Hospital on Nov. 3rd, 1896; an abscess formed and broke below the internal malleolus, leaving a sinus which was discharging. A probe indicated carious bone. The patient was in much pain and was subject to starting at night; the temperature in the evening ran up to about 101° F. A week later no improvement had resulted from rest; the boy looked worse, was losing weight, and was in much pain. On the 11th, under chloroform, Dr. Collins performed Pirogoff's amputation of the foot. The sawn surfaces of the tibia and os calcis appeared to be healthy to the naked eye, and were brought into accurate apposition by silk sutures passed through foramina bored with a brad-awl. The wound healed well, though the temperature ranged high for a week or two. On Jan. 2nd, 1897, he could walk without a boot and was gaining weight rapidly. When fitted with a dummy foot he walked without any lurch, and so well that some who saw him could not believe that the foot had been amputated.

Sketch showing relative lengths of stumps after Syme's and Pirogoff's amputations.

Remarks by Dr. COLLINS.—The Moscow meeting will doubtless afford occasion for reviving the fame won by Nikolaus Pirogoff in many fields of human activity. As a profound anatomist, a military surgeon, a hospital organiser, and a university reformer he has impressed his rugged personality upon the history of his time. True, that to the ordinary English student his name is known almost exclusively by his osteoplastic modification of Syme's amputation, of which an account with a diagram is to be found in his "Klinische Chirurgie," published at Leipzig in 1854. But this improvement in amputation of the foot, as he practised it, as also as more recently modified by Lefort and Günther, was in itself a valuable reform. I recently happened to have in my wards two children of about the same age and height; in one case I performed Syme's amputation as the caries was too extensive to save any of the tarsus, and in the other case (the notes of which are given above) I performed Pirogoff's modified operation. It occurred to me to photograph the patients side by side. The accompanying illustration (which I have reproduced faithfully from the photograph) shows the advantage in length in the case of the boy as against the shortening in that of the girl, in which Syme's unmodified operation was done. The difference in the gait was not less noticeable even when the shortening in the latter case was corrected by a cork sole.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.



A CASE OF RELAPSING PNEUMONIA.

(Under the care of Dr. THOMAS OLIVER.)

A MAN, aged twenty-three years, was, on Nov. 26th, 1896, admitted into the Newcastle Royal Infirmary under the care of Dr. Oliver. As the patient was delirious no history of the illness was at this stage obtainable, except from the remark volunteered by a friend that he had been in bed for five days. Subsequently when he recovered it was ascertained from him that while at work on the 21st he had been suddenly seized with a violent shivering at 11 A.M., that do what he might he could not get himself warm, and that in the afternoon he felt so unwell he was obliged to go to bed. On the morning after his admission into the infirmary he had a flushed face and rapid breathing, his mind was still wandering, and he was the subject of short cough and rusty expectoration. He was too ill for a careful examination to be made. All that could be done, therefore, was to make an examination of the front of the chest, by which was detected a limited area that was dull on percussion, commencing a few inches below the right clavicle, and over this area distinct tubular breathing could be heard. The left chest and heart were healthy. On the 28th, while there was evidence of the percussion note over the upper part of the right chest being less dull, there was detected a small area of dulness external to the right nipple and also that the base of the lung was dull. The area which gave this altered percussion note extended in an upward but slanting direction towards the axilla. On examining the chest posteriorly tubular breathing could be heard from the inferior angle of the right scapula downwards. Although the breathing was rapid (56 to the minute) there was no actual dyspnœa, the pulse was 110, and the temperature was 102° F., having fallen 2° since the previous night. Later in the course of the day there was a considerable degree of muscular twitching, but this disappeared on discontinuing the liquor strychninæ which for the past two days he had been taking. On the 30th he seemed to be rather better. His temperature on the previous afternoon was 105·2°, but by midnight it had fallen to 98·4°, and with the fall of his temperature the delirium disappeared. For brevity's sake, although the four hours' chart is quoted from, it is not reproduced. For the next two days the patient seemed on the whole to be fairly well; but although his temperature had fallen he never exhibited that look of well-being which is discernible in any one who, having passed successfully through a sharp illness like pneumonia, may be said to have "turned the corner." He was heavy and listless, so much so that when, after remaining thus for a few days, and the temperature again began to rise, and the dulness at the right

Digitized by Google

base had extended to the sixth rib, the possibility of a commencing empyema suggested itself. On Dec. 5th the patient was the subject of a short hacking cough. The respiration was 32 and the pulse was 100; the tongue was coated. There was slight diarrhœa, the stools being thin and watery, yellow, and of a disagreeable odour. Although his temperature on the previous night was 104·5° he was stronger than he was and abler to bear examination. The dulness previously detected at the level of the third right rib had entirely disappeared and the percussion note was now almost hyper-resonant. There was still dulness at the extreme base of the right lung. Over the upper part of the right lung the breath sounds were coarse and accompanied by muco-crepitant râles, while at the base a friction sound was heard and there was rather a deficiency of the respiratory murmur. Beyond a degree of coarseness and loudness of the breath sounds the left lung presented nothing abnormal. The heart was healthy and there was no splenic enlargement. On examining the chest posteriorly the dulness at the right base was most marked in the axillary line, and here the respiratory murmur was deficient. As the physical signs suggested pleural effusion a needle was inserted into the right chest, but only a few drops of dark venous blood were withdrawn. On the 8th there was very marked tubular breathing with increased vocal fremitus and vocal resonance over the extreme right apex, back and front, but especially posteriorly. On the 10th the patient was bathed in perspiration; his breathing was less rapid and his condition, generally speaking, was favourable. On the 11th he still perspired very freely. He had apparently passed through a second attack of pneumonia, in which the temperature began to fall on the sixth and seventh days. On the eighth it was subnormal (97·4°), the pulse was 65, and the respiration was 24. He looked pale and was prostrate. He had the look of a man who had passed through a severe illness, but with it all he had a clearer and brighter expression than he had ever had since his admission. On the occasion of his first crisis the observer was struck by the want of mental clearness, but in this there were a brightness and intelligence which were not present previously. There was still cough, and the sputa were now muco-purulent. It is interesting to note that in the second attack of pneumonia the sputa, which had lost their typical character, again became rusty on the second day of the illness and continued thus until the sixth. On examining the blood after the first crisis there was almost a complete absence of leucocytes, but in this, although a few more were observed, there was still a very noticeable deficiency. The patient's prostration was still too great to allow of any lengthened physical examination, but there could be detected dulness over the right apex, crepitation and bronchial râles, with tubular breathing. On the 14th, although looking pale, the patient was progressing satisfactorily. There was still profuse perspiration; the pulse was 60, and the respiration was 24; the temperature for the past four days had been sub-normal. The expectoration was becoming increasingly less purulent and more mucous, and was gradually diminishing in quantity. Over the right apex there were heard coarse bronchial breathing and large crepitant râles. The heart and the left lung were healthy. The urine throughout the illness had been free from albumin and sugar. On the 19th the patient looked and felt remarkably well; he had an excellent

Digitized by Google

appetite, and there was no cough or expectoration. The right chest was resonant from the clavicle to almost the base of the lung; the respiratory murmur was full and free, and there was no longer any râle heard in front except at the extreme base, where occasionally a friction sound could be detected during inspiration. In the axillary line there were diminishing dulness at the base, friction sound, and feeble respiratory murmur. These by degrees gradually disappeared, and the patient made an excellent recovery and has maintained (August, 1897) his health since.

Remarks by Dr. OLIVER.—Whatever view we hold as to the nature of a recurrence of acute pneumonia in a patient a few days after his apparent recovery, the fact is sufficiently uncommon to attract attention and to merit the few remarks I feel disposed to make upon it. Typical as pneumonia frequently is, it still exhibits many peculiarities, particularly as regards its duration and crisis. A relapse occurs occasionally and may even be repeated. Under most circumstances it is not always easy to distinguish a relapse from a pseudo-crisis, from pneumonia progrediens, or from a form spoken of as migratory and defined by Homburger as a pneumonia which in its course shows successive invasion of different parts of the lung, while the physical signs disappear from the parts first affected. To constitute a true relapse there must have been complete apyrexia and more or less advancing resolution. Osler alludes to pneumonias in which after the subsidence of fever any time between the ninth and eleventh days, and when the temperature has remained normal for a day or two, it again rises and persists for eight or ten days. The second attack is said to be mild, the duration of the pyrexia in the relapse being usually shorter than in the primary illness by several days. Since a true relapse is a rare occurrence we have some difficulty in really knowing what it means. Walshe, in dealing with the question of the frequency of relapse in pneumonia, states on the authority of Briquet that it occurs in one-fifth, and according to Grisolle in one twenty-eighth of the cases. Our experience certainly leads us to say that Briquet very much overstates the frequency, and, without expressing the ratio in numerical terms, we would simply state that a true relapse announced by a fresh rigor, rusty expectoration, crepitation, and a well-defined period of pyrexia is in this country a very much rarer circumstance than these French physicians would lead us to believe. The patient whose illness supplies the above facts was a young, strongly built, and apparently healthy man, but of such an age as to have sometimes raised in my mind during the course of his illness the question as to the possible existence of a deeper constitutional malady than pneumonia. It is noteworthy that the relapse was not ushered in by a rigor, but by a fairly rapid rise of temperature and an increased number of respirations; that the sputa became rusty on the second day; that the pyrexia lasted about seven days, terminating in a lysis accompanied by profuse perspiration; and that, just as in a primary attack of pneumonia, the physical signs in the chest lagged behind those indicating constitutional disturbance. Some time ago Dr. A. E. Wright,[1] in a paper on the Bacteriology and Pathological Chemistry of Pneumonia read before the Pathological Society of London, showed how, as the crisis in this illness was reached, there occurred the triple phenomenon of disappearance of leucocytes and bacteria from the blood, accompanied by tumefaction of the spleen. In my patient the disappearance of leucocytes from the blood after the pseudo-crisis was very noticeable, also after the relapse; but there never occurred any perceptible enlargement of the spleen.

[1] THE LANCET, Feb. 9th, 1895.

NORTH DEVON INFIRMARY, BARNSTAPLE.—The annual meeting of the North Devon Infirmary was held in the board-room on Aug. 24th, Lord Ebrington being in the chair. The report showed that on June 30th, 1896, there were 44 in-patients remaining under treatment; 691 were admitted during the twelve months, 23 died, and 657 were discharged, leaving 55 under treatment on June 30th, 1897. The out-patients were 2967 in number. The average daily number of in-patients was 51, the average period of residence being between 25 and 26 days. The total income was £3318, including £1211 balance at the banks last year; the expenditure, however, had materially exceeded the income, so that it was necessary to withdraw £500 from deposit.

Reviews and Notices of Books.

Allgemeine Dermatologie, oder Allgemeine Pathologie, Diagnose und Therapie der Hautkrankheiten. (General Dermatology, or General Pathology, Diagnosis, and Therapeutics of Diseases of the Skin.) Von Dr. ERNST KROMAYER. Berlin: Borntträger Brothers. 1896. Price 10 marks.

THIS book, published in the form of lectures, will afford to those acquainted with the German tongue a very useful introduction to diseases of the skin. As its name implies, it treats the subject from the general point of view only. Descriptions of special diseases form no part of its scheme, and diagnosis and therapeutics are dealt with from a broad and general standpoint also. The first part of the book treats of general pathology in its relation to the skin, and the writer justly points out that, owing to its superficial position and accessibility to observation, the skin offers a peculiarly favourable field for the study of pathological processes. The first two lectures are devoted to a detailed account of the structure of the skin and its appendages, illustrated by useful diagrams and micro-photographs. The author then passes on to the subjects of active and passive hyperæmia and anæmia of the skin; the account of atonic hyperæmia is a very excellent and lucid one. Subcutaneous and papillary œdema are next dealt with very thoroughly. Inflammation receives attention in three lectures, in which the subject is treated at considerable length and in a scientific spirit. In the next two lectures the author deals with the pathology of the chronic papular and tubercular eruptions, grouping them together on the ground of their common basis in tissue proliferation; the widely different nature of such diseases as tuberculosis, psoriasis, and ringworm leads us to doubt the expediency of such a classification, however excellent the description of the pathological processes in question may be. Hypertrophy, atrophy, pigmentation, new growths, and ulceration form the subjects of the remaining lectures of this the largest section of the book. The section on general diagnosis comprises two lectures only, in which the writer discusses the principles upon which the genus, rather than the species, of the disease is to be determined. The third section consists of three lectures, in which are set forth the principles of dermatological therapeutics and the mode of action of the different groups of remedies. Both these sections are well worthy of attentive study.

We know of no book in the English language, and, indeed, no book of such moderate size in any language, which has precisely the scope and aim of the one before us. We are, indeed, sadly lacking in short but thorough introductory treatises of the kind. No one after reading Dr. Kromayer's lectures can fail to bring to the diagnosis and treatment of skin diseases a clearer mind and a more rational and scientific spirit. We can recommend it heartily to all who can read it in the original, and we trust that it may be worth someone's while to translate it for the benefit of those who are unfamiliar with German.

Manual of Static Electricity in x Ray and Therapeutic Uses. By S. H. MONELL, M.D. New York: W. B. Harison. 1897. Royal 8vo. Pp 614.

THIS book has a threefold interest, first, because it is the most important book in the English language on Modern Applications of "Statical" Electricity to Therapeutics; secondly, because it supplies reprints, most useful for purposes of reference, of the reports of Addison, Golding-Bird, and Sir William Gull on the subject of statical treatment in the earlier part of this century; and, thirdly,

Digitized by Google

because it draws attention to the advantages of the electrostatic machine for x ray work.

In England the excitation of x ray tubes by electrical machines seems to have been tried and abandoned, the probable reason being that good machines are extremely uncommon in this country. Theoretically, an apparatus capable of supplying a steady electro-motive force high enough to excite the tubes should present advantages over the intermittent current of the induction coil, and practically it is so. With a good Wimshurst machine there is a brilliant illumination of the phosphorescent screen far superior to the flickering light given by a coil, and time is saved in exposures of photographic plates. Dr. Monell claims to have procured with five minutes' exposure results as good as could have been obtained in half an hour with coils. He writes with confidence and is evidently an experienced worker with the x rays. A machine with twelve 36 in. plates is the size which he finds best, and though his work was done with a Holtz machine (the type most used in the States), the Wimshurst machine is certainly as good and probably is better for the purpose.

Turning now to his account of the therapeutic uses of electrostatic treatment, we find much which is calculated to afford food for thought. In England the statical machine has not yet been seriously taken up, but it is evident that Dr. Monell finds in statical treatment a most valuable agent for the relief of rheumatic and other painful states, such as neuralgia and sciatica; also in neurasthenia and in melancholia and other morbid mental conditions, where he finds it to have a general tonic effect which is productive of good.

The style of the book is spirited and practical; it supplies a want, and should lead to a further study of electrostatic methods in this country.

LIBRARY TABLE.

Tuberculosis, or Flesh-eating a Cause of Consumption. By JOSIAH OLDFIELD, M.A., B.C.L. The London Vegetarian Society, Memorial Hall, Farringdon-street, E.C. 1897. Pp. 62. Price 6*d*.—The principal question discussed in this little book relates to the trustworthiness of official inspection as a means of recognising tuberculous meat. The author concludes that a large proportion of the carcasses which are passed by the inspectors are nevertheless sufficiently infected with tubercle to be dangerous to the consumer, and that the system is almost worse than useless, for it deludes the public into relying on a security which is non-existent. He points out that the ordinary cooking of meat does not necessarily destroy the tubercle bacillus and its spores, and he advocates vegetarianism as a complete solution of the difficulty. At the same time he recommends a much more careful and thorough examination of meat than is at present enforced, together with compensation to butchers who find that the animals which they have bought are diseased.

Mrs. Keith's Crime. By Mrs. W. K. CLIFFORD. London: T. Fisher Unwin. 1897. Price 6*s*.—This is a new edition of a powerful if sombre work which appeared first in 1885. On its first appearance some interest was aroused among medical men as to the exact nature of the complaint from which the heroine suffered, opinions being pretty equally divided between a mediastinal tumour and some form of morbus cordis. In any case, it is a rare occurrence to find medical matters treated in lay writings as correctly as they are in this book.

In the *Phonographic Record* for August Dr. Colman tells how a case of intense pain in the hand and arm after lasting for five months was cured by rest and continuous irrigation for ten days with weak spirit and water. Sir W. R. Gowers asks for information as to the duration of the blue line in lead poisoning, and Mr. Peyton Beale emphasises the importance of purification of the skin of the patient and the hands of the surgeon before an operation. When wounds become inoculated with micro-organisms at the time of an operation, in nearly every case the micro-organisms come from the hands of the surgeon; and Mr. Beale thinks that in nine-tenths of the operation wounds which go wrong the inoculation with septic organisms takes place at the time of the operation. Short notes and a reference to medical phonography in Australia, where Dr. Grant, who has used shorthand for a quarter of a century, testifies to its advantages, complete the number.

JOURNALS AND REVIEWS.

Brain: A Journal of Neurology. Parts 77 and 78. Spring and Summer, 1897. London: Macmillan and Co., Ltd.—It seems to us a pity that the abundant material apparently at the disposal of the Neurological Society should be as it were saved up until there is sufficient to make a double number of *Brain*. The amount of reading in over 250 pages of neurological material is considerable, and we venture to think that the society would consult the convenience of all readers of *Brain* if it reverted to the excellent custom of issuing more or less regularly its single quarterly numbers. The double number before us is one of much interest. Dr. Savage's presidential address on Heredity and Neurosis occupies the first place. Dr. Michell Clarke next has an article on the curious disease known as Huntington's Chorea, and there are numerous other clinical and experimental records by Dr. Risien Russell, Dr. Wiglesworth, Professor Hill, and others. One of the most important papers is probably that of Dr. F. E. Batten dealing with the muscle spindle under pathological conditions. There are several reviews of neurological and psychological works, and a comparatively novel feature is a short abstract of the proceedings of the Neurological Society.

SOCIETY FOR THE SUPPRESSION OF THE OPIUM TRADE.—We have received the report of the annual meeting of the Society for the Suppression of the Opium Trade, which was held at the Memorial Hall, Farringdon-street, E.C., Sir Joseph W. Pease, Bart., M.P., presiding. It mentions that the majority report of the Royal Commission on Opium recommended that the Indian Government should abandon in all provinces the licensing of shops for the manufacture and sale of opium-smoking preparations, and this reform has now been carried into effect. The Indian Government has also undertaken to ascertain the opinions of local governments on the question of legislation against the use of rooms as smoking saloons, but the replies received from the various local governments have not yet been presented to Parliament. Information, however, has reached the Society from reliable sources to the effect that the opium-smoking establishments have in fact been closed almost all over India, apparently without any fresh legislation. To the great mass of the Indian population the closing of these places means the suppression of opium-smoking, as in India very few have the skill or the facilities for preparing opium for their own smoking. Another measure, enacted at the close of 1896, is that by which in the Straits Settlements the Malay population has been excluded from such places, and thus practically protected from the opium vice altogether, as opium is not usually consumed there in any other way. Another race among whom the use of opium has recently been prohibited are the Chins of Upper Burmah, imprisonment or fine, or both, being the punishment for cultivating or dealing in opium, ganja, or bhang in the Chin Hills. The report goes on to state that the Indian Government, although it is endeavouring to check opium smoking in India, nevertheless prepares in its own factories, and sells for export every year, mainly to China, 36,000 chests, containing 5,040,000 lb. of opium specially prepared to suit the taste of Chinese smokers.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 4, 1897.

THE first meeting of the British Medical Association beyond the limits of the four seas is naturally an event of special mark, and it is fitting that in this year of Empire the meeting place chosen should have been the greatest of our self-governing colonies. The note of unity was prominent in the addresses of Dr. RODDICK and Dr. OSLER, reports of which will be found in another column. The President took for the main subject of his address the Medical Aspects of Canada—a wise selection, for we fear that to most of the British delegates that great country is almost an unknown land. Some few books have been published on this side dealing with it, notably the delightful work of EARL MILTON and Dr. CHEADLE, and the "Great Lone Land" of BUTLER; but even these are not well known, and both, if we remember rightly, appeared some thirty years ago. The natural resources of Canada are very remarkable, and her special feature—namely, the enormous area of water-way—is to be matched in no other land, save possibly Finland. British practitioners will owe Dr. RODDICK a debt of gratitude for the clear and concise way in which he has summarised the advantages of his country.

The subject of Professor OSLER'S address in Medicine was a very fitting theme for a meeting held in a great British colony. He dealt with the growth of medical knowledge in the English-speaking countries beyond the seas. The nearest parallel to the Greater Britain which has grown up within the last three hundred years is to be found in Magna Græcia, and as the Grecian cities scattered about the shores of the Mediterranean looked for help and support from the Greece they had left, so the early British colonies received their knowledge and their learning from the land whence they themselves had come. Hardly three centuries have elapsed since the revival of medicine in England, and three names naturally suggest themselves as representative of the progress which has come from that revival. LINACRE, HARVEY, and SYDENHAM are typical of the literary, the scientific, and the practical aspects of modern medicine. LINACRE comes first in point of time; not only was he in a large measure responsible for the revival of Greek thought in England, but he was also directly the cause of the more careful study of HIPPOCRATES and GALEN in the original. The truly scientific character of so much of GALEN'S work formed a most striking contrast to the crude empiricism which was current in LINACRE'S day, and in rendering available once more this ancient knowledge LINACRE prepared the way for his successor HARVEY. The revival of the study of the Greek Medical Classics could not but benefit and assist the careful scientific study of medicine. HARVEY'S great discovery of the circulation of the blood was in a way an outcome of the further consideration of the methods of the "father of medicine," and this discovery was itself the true foundation of modern experimental physiology.

If there is any special quality which may be said to be characteristic of the British it is certainly the practical nature of all their work, and so HARVEY did not content himself with remaining a theoretical physiologist—he was also a practising physician; and though the public of that day is said not to have appreciated as it should this union of the science with the art of physic, yet the union cannot but have been beneficial to medicine itself. The same tendency has been seen even up to the present day; those who have done most for physiology and the allied sciences have been for the most part engaged in the practice of medicine or surgery. We turn to the third member of the triad. If we may look upon HARVEY as typical of the science of medicine we may regard SYDENHAM as a good representative of the practical physician of to-day. At the start he was weighed down by the accumulations of many centuries of false facts and baseless theories; these he resolutely put aside, and in the very spirit of HIPPOCRATES he applied himself to the exact and careful study of the phenomena of disease; the practical nature of SYDENHAM is seen in all his work, and though we may not claim for Britain the distinction of advances in the scientific aspects of medicine, such as can be claimed by the countries of LAENNEC, PASTEUR, VIRCHOW, and KOCH, yet all the most important practical advances, as vaccination, anæsthesia, and antiseptic surgery, are the products of the English-speaking countries.

Professor OSLER divides the development of medicine in North America into three periods. In the first period, which may be considered to extend from the foundation of those colonies to the year 1820, all the medical knowledge was derived from the mother country, and until the formation of medical schools in America, commencing soon after the middle of the eighteenth century, the supply of medical men was derived almost entirely from Great Britain, and many colonists came to London and Edinburgh to study medicine. In this way the teaching of HUNTER had a very far-reaching effect; his former pupils included many of the foremost physicians of America, and reprints of his works were circulated widely. The second period may be considered to extend from 1820 to 1860. The important advances in clinical medicine due to the researches of BICHAT, BROUSSAIS, and LAENNEC naturally attracted many American students to Paris, and the influence of the French school could not fail to be deep and wide; in this way Great Britain lost much of the influence she had formerly possessed, but even during this period medical literature in America consisted almost entirely of reprints of English works. The third period Professor OSLER considers to extend from 1860 to the present time, and it is characterised by the growth of appreciation of the German school. In 1860 appeared in America the first translation of VIRCHOW'S "Cellular Pathology," and the stream of American students turned in the direction of Berlin and of Vienna.

In Australia the majority of those practising medicine have received their professional education in Great Britain, but medical schools have now for a long time been established and the number of native-trained men is yearly

Digitized by Google

increasing. India is a vast field for medical research, and Professor OSLER expressed his great regret that the British Government had not done much more than it has to aid the scientific investigation of disease in that country. What the future may bring forth, who can say? No one in 1797 would have ventured to predict that the present year would see such gatherings as have just been held at Montreal and at Moscow, and to science is due the honour of first having united for one common cause men of different race, speech, and creed. Professor OSLER regretted that the literary aspects of medicine had not received of late years the attention in Great Britain which they deserved, but when we have the privilege of reading such an eloquent, learned, and scholarly address as that which he delivered at the Montreal meeting we cannot but think that there are worthy successors of LINACRE at the present day.

Mr. MITCHELL BANKS, who delivered the address in Surgery, took for his subject the military surgeon. At the present time, when the British Government finds it impossible to obtain a sufficient number of surgeons for the army, it is very useful to consider what has been the position of the army surgeon in past times. Some very interesting particulars were given of our scanty knowledge of the surgeons attached to the cohorts and legions of the Roman army; all our information is derived from a few votive and mortuary tablets. Mr. MITCHELL BANKS gave AMBROSE PARÉ his due share of credit for the reforms he effected in the treatment of wounds, and then he went on to speak of PETER LOWE, who, after having seen a great deal of practice in military surgery in France, returned to Glasgow, where he founded the Faculty of Physicians and Surgeons. At the end of the sixteenth century he published a "Treatise on Surgery," in which he expressed very sensible views as to the treatment of gunshot wounds; his methods of arrest of hæmorrhage were good, for he advised the actual cautery if the wound was foul, but a ligature if the wound was sweet. Thirty years later WOODALL'S "Viaticum" appeared, which is of interest as the first English work specially devoted to military surgery. A name which is even better known is that of RICHARD WISEMAN, who served as surgeon in the armies of CHARLES I., and published in 1672 a "Treatise on Wounds." A very interesting account was given of Baron LARREY, NAPOLEON'S great surgeon, who served with much distinction in the Russian and Waterloo campaigns. The danger of death in a naval or military expedition was formerly much greater from disease than from wounds, and several instances illustrating this fact were quoted. On the field of battle military surgeons run at least as much risk as the members of those branches of the army which are specially called "combatant," and members of the medical staff have received a larger proportion of Victoria Crosses than the other branches of the service. Many instances of the great courage displayed by army surgeons were mentioned, and similar gallant deeds to those related will without doubt be performed whenever the occasion shall arise.

INTRA-TRACHEAL medication has been extensively tried by numerous observers. Some physicians have been fully satisfied with the results; others, however, have found that not only does this method of applying drugs to the respiratory apparatus cause considerable discomfort to the patient, but no better results are obtained than when the drugs are given in the usual way by the mouth. These remarks, of course, do not apply to laryngeal medication. In the *Journal of the American Medical Association* of June 26th a paper appears by Dr. J. A. THOMPSON, of Cincinnati, detailing the results of his experience of tracheal injections, which has been very large, and his conclusions are decidedly favourable to that mode of treatment. He considers that there are several reasons for the slow growth of this manner of treatment in professional favour, the principal one being that few physicians are sufficiently expert in the examination and treatment of the upper air passages to employ it. Possibly there is some truth in this statement, and it may account in some measure for the discomfort experienced by the patients after an injection has been administered; if properly given very little, if any, inconvenience is experienced. Dr. THOMPSON claims for this method of treatment several advantages. In the first place, he says, we get the direct local action of the medicines on the diseased areas, and he instances bronchiectasis as being particularly suitable for tracheal injections. He is of opinion that "no medicine given by the mouth will prevent the decomposition of the secretions in the dilated bronchi; the odour and the absorption of septic material from them cannot be controlled. A few tracheal injections will usually disinfect the cavities so that the odour disappears." With these remarks we agree; but whether this principle of local action can be extended beyond dilated bronchi is doubtful. If a large tuberculous cavity communicates with a bronchus it is possible that a tracheal injection of guaiacol might prove beneficial; but that the drug acts locally on the lung tissue itself, especially at the apices, has by no means been proved.

Another point brought forward by Dr. THOMPSON is well worthy of consideration. Medicines used by tracheal injections are not changed by passing through the digestive organs into unknown compounds, and for this reason we can be more certain of their action. "No one would think of treating a tuberculous laryngitis by internal medication alone. There is just as much reason for applying medicines of known beneficial local action directly to the lungs as there is for using them in the larynx." The weak point in this suggestion is that we cannot get at the diseased portions of the lungs as we can at the larynx, but at the same time if guaiacol has a local action on tuberculous deposits, if the injection is well tolerated, inspiratory efforts may carry the drug some little distance into the lung, and some of it may be absorbed by the parenchyma of the lung, and so the desired effect be produced. Dr. THOMPSON also points out that when medicines are injected directly into the trachea they have no deleterious effect on the organs of digestion. Guaiacol and similar preparations frequently produce ill effects when taken by the mouth, and have to be discontinued; so also various expectorants, such as are used in acute and sub-acute catarrhal diseases, act injuriously on the stomach and intestine. The name of one class, nauseating expectorants, testifies to the universal recognition of this fact.

The diseases most suitable for this form of treatment,

Digitized by Google

according to this writer, are pulmonary tuberculosis, pulmonary syphilis, chronic bronchitis, inflammation of the trachea, asthma, and bronchiectasis. Tracheal injections have been most extensively tried in pulmonary tuberculosis and with varying success by different observers. Dr. THOMPSON speaks very highly of this method in chronic bronchitis. He believes "there is no comparison between the two methods of treatment. The results are so much more rapid and satisfactory by intra-tracheal medication that no patient who has once been given this treatment is ever willing to continue internal medication." The most serviceable solutions are menthol (2 per cent.), guaiacol (1 per cent.), creosote (1 per cent.), and camphor (from 2 to 3 per cent.). The vehicle used should be one of the light petroleum oils or olive oil. The method will doubtless be given an extended trial, and the experiences of other physicians will be awaited with interest.

WE have so often found fault with the loose manner in which medical education and medical practice have been conducted in the United States of America, that it is only fair to be ready to recognise a healthier and more creditable state of things in that country when such an occasion arises. We find such an instance reported by, and commented on in, our contemporary the *New York Medical Record* of Aug. 21st. The case in point occurred in Louisville, Kentucky—a state creditably known in respect of its medical legislation and, what is more, of the application of such legislation. For more than twenty years—namely, since 1874, Kentucky has had a law regulating the practice of medicine in the State, one or two clauses of which we may insert as a guide to those who are impressed with the inadequacy of our own Act.

Clause 2 of the Act of 1874 and amended in 1888 is as follows:—

"That on and after the first day of April, 1889, it shall be unlawful for any person to practise medicine in any of its branches within the limits of this State who has not exhibited and registered in the county clerk's office where he is practising or intends to commence the practice of medicine his authority for so practising medicine as prescribed in this Act."

Clause 3 prescribes the authority to practise under the Act, viz.: (*a*) a reputable diploma from some legally chartered school of the State or from a foreign country; and (*b*) an affidavit claiming exemption on the ground of having been in practice before 1884.

Clause 8 is as follows:—

"Any person living in this State, or any person coming into this State, who shall practise medicine or attempt to practise medicine in any of its departments, or who shall perform or attempt to perform any surgical operation for or upon any person within the limits of this State *for reward or compensation* [the italics are ours] in violation of the provisions of this Act shall, upon conviction thereof, be fined fifty dollars, and upon each and every subsequent conviction shall be fined one hundred dollars and be imprisoned thirty days, or either, or both, in the discretion of the jury; and in no case where the provisions of this Act have been violated shall the person so violating be entitled to receive compensation for services rendered."

A valuable clause in the same sense was "approved" on May 24th, 1890, which ran as follows:—

"Nothing in this Act or the Acts to which this is an amendment shall be so construed as to authorise any travelling empiric to register or practise medicine in any county in this State: to open office for such purpose, or to announce to the public in any other way his readiness to practise medicine in any of its branches in any county, shall be to engage in the practice of medicine within the meaning of the law."

Such is the law in Kentucky; and so long ago as 1890 Dr. J. N. MCCORMACK, Secretary of the Kentucky State Board of Health, testified that it was working well with the approval alike of the profession and the public, and that four or five hundred men had been forced to retire from practice or leave the State. Writing in reference to the case alluded to below, he gives a report significantly different from the dispiriting reports of all those who try to use our lame legislation for the repression of quackery and the vindication of regular practice, though our system of medical education and registration is, of course, very much more exacting than that of Kentucky. He says: "Our law has now been in operation nearly four years. It has been tested upon every point, and, so far, we have not failed to secure a conviction in each case tried. We convicted the Copeland people, the K. and K.'s, and all other concerns of that kind doing business here, and are able to report that there is not now an itinerant or advertising doctor within the limits of this State." When shall we be able to say the same of the United Kingdom? It only remains for us to state the particulars of the case which has called forth this striking testimony to the efficiency of the law of Kentucky. First let us say that it was brought into court by the Kentucky State Board of Health. It was that of a member of the bone-setting fraternity who styled himself "a Professor of Osteopathy" and who was charged with practising medicine within the meaning of the Act of the State. He sought to meet the charge by saying that he was "not practising medicine," but "simply manipulating the muscles with the hands." Good, simple man. Unfortunately for him, Judge THOMPSON was not so simple, but considered "that in his ignorance of the fundamental principles of the profession he subjected the child, who was suffering from tuberculous disease of the hip, to cruel and unnecessary torture, affecting his health and necessitating the employment of a physician to treat him for fever resulting from his ineptitude." The court ruled—and the ruling is expected to be a precedent in future cases—that "any person who *for compensation* professes to apply any science which relates to the prevention, cure, or alleviation of the diseases of the human body is practising medicine within the meaning of the statute." No wonder that good law, construed with so much force and common sense and so protective of suffering humanity, is popular with the public as well as with the profession.

Annotations.

"Ne quid nimis."

INSUFFICIENCY OF THE 40TH CLAUSE OF THE MEDICAL ACT.

A CASE is reported, in the *Accrington Gazette*, showing the hopelessness of prosecutions under the 40th Section of the Medical Act. The defendant was John Haworth, of 366, Blackburn-road, Accrington, charged with falsely

Digitized by Google

implying that he was recognised by law under the Medical Act, 1858, Section 40. Mr. Haworth was not unknown to the Bench or to Accrington, for in 1896 he was fined 40*s.* and costs for a similar offence. The facts were very simple. The defendant had on the fanlight over the front door the words, "Dr. Haworth, Homœopathic Physician," in gilt letters; and on the brass plate on the front door of the house the words, "Dr. Haworth, Homœopathic Physician and Massage Institute." On the outer gate of the house was a brass plate with the words, "Dr. Haworth, M.D. Canada"; the word "Canada" was under the words "Dr. Haworth, M.D.," and in very small letters, not to be made out by persons standing any distance from the plate. The chief defence was that the word "Canada" made all the difference and enabled persons to see that the defendant made no pretence to be recognised by English law as a medical man. Another point in the defence was curious and not very complimentary to homœopathic practitioners. Mr. Sutcliffe, representing the defendant, said there was not a fully-qualified medical man or registered practitioner in Accrington, or even in Lancashire, who used the words "homœopathic physician." He really made a point of this as showing that "Dr. Haworth" made it clear that he was not a qualified medical man within the meaning of the Act. On such weak grounds Mr. Sutcliffe defended his client, who called himself "a physician" and M.D. in two instances without even the qualification of the word Canada, which in this bare form means absolutely nothing. The diploma was said to have been procured after examination from a university in Canada. But it was not produced, and the magistrate's clerk advised the Bench to take no notice of it. We should have thought the offence very obvious. But the Bench was hopelessly, because equally, divided. What will Mr. Muir Mackenzie say to this fresh illustration of the insufficiency of the 40th clause, and to which moiety of the Bench of Accrington will he award praise? Meantime the British public are effectually deceived, and the vagueness of Acts of Parliament is painfully demonstrated.

CHLOROFORM IN DENTAL PRACTICE.

A DEATH under chloroform occurred at Rhyl on Aug. 13th under circumstances which confirm our often expressed opinion that chloroform is not a desirable or safe anæsthetic for dental practice. The patient in this case was a woman, aged twenty-nine years, in good health, and described as being strong and free from fear of the anæsthetic. She had very bad teeth, and a local dentist advised the extraction of twenty-seven of them. A medical man was called upon to give an anæsthetic, and he advised the use of chloroform. In his evidence[1] he said that he had examined the patient and judged she was in a fit state to take the anæsthetic. He considered nitrous oxide gas would be insufficient for so extensive a clearance, and added: "It was quite a usual thing to administer chloroform in cases of dental surgery which occupied some time, *and chloroform was as safe as any other anæsthetic.*" It is to be presumed that this statement, besides its general application, was meant in particular to apply to dental surgery, and it is in this connexion that we cannot but feel so sweeping a pronouncement is hardly in consonance with either the facts of this particular case or with the experience of the last fifty years. To refer for one moment in detail to the case. The patient was placed in a chair, and after the chloroform had been given from a mask for fifteen minutes the medical man signed to the dentist to commence the extractions. This was done, and after three teeth were removed the operator was requested to stop, as the patient had become "blue in the face" and "the breathing had stopped." It is further stated that just before the operation the patient struggled slightly, "as was usual in cases of the sort." They lifted the patient out of the chair, "but she was dead three or four minutes after she was placed on the floor." It would seem, therefore, that when the patient struggled she was not fully under chloroform, and this was after about thirteen or fourteen minutes of inhalation, then she at once became fully under the influence of the anæsthetic and the operation was proceeded with. Probably during that struggle the overdose was inhaled, and the interval before the chloroform actually stopped respiration by its action upon the medullary centres was taken by the dentist in drawing three teeth. It is obvious that the actual manipulation of the tooth extraction interferes both with respiration and the proper watching of the chest movements. Many medical men on such occasions assist their dental colleagues by holding the patient's head, and so have their attention withdrawn from the function of respiration and the condition of the patient. These are manifest objections to using chloroform, and a still further one is that it has been shown that the sitting position is one which increases the patient's risk under that anæsthetic. But the most cogent adverse reason to the use of chloroform in such cases is the extremely high mortality which reference to the report of THE LANCET Commission appointed to Investigate the Subject of the Administration of Chloroform and other Anæsthetics from a Clinical Standpoint, in 1893, shows only too plainly. We cannot agree with any statement that chloroform in dental operations is as safe as ether or the A.C.E. mixture. It is a very great question whether it is wise to attempt to remove twenty-seven teeth at one sitting; but if cases do arise in which such an heroic proceeding is considered justifiable, then certainly ether or a mixture should be used rather than chloroform. The only way in which the last-named anæsthetic can be at all safely employed in dental surgery is where the patient is placed under the same conditions as if he or she were about to undergo a major surgical operation. This cannot be done in the ordinary routine work of the dental surgery. The patient must be prepared by abstention from heavy food, must have all clothing absolutely removed and replaced by a dressing-gown, and must be placed in the recumbent position. We cannot but feel that for so comparatively trifling a matter as having teeth out no one's life should be jeopardised by the use of chloroform unless the fullest precautions are taken and the risk looked clearly in the face. Many country dentists may point to a large experience of chloroform without mishaps, but their fortunate cases cannot counterbalance or lessen the horror of a fatality such as that at Rhyl. We cannot speak too emphatically. This case is almost identical with one which happened only recently and which was recorded in our columns.

[1] Liverpool Mercury, Aug. 16th, 1897.

THE DUKE OF DEVONSHIRE ON HOSPITALS AND NURSES.

THE Duke of Devonshire may always be trusted to seize the prominent points of a question and treat them in the most practical fashion. He gives indication, too—if not always expression—of a sense of humour beneath the more obvious meaning of his words. His primary duty at Bradford on Monday was to lay the corner stone of the new nurses' home at Bradford in connexion with the infirmary there. This, of course, involved a few words on the subject of nurses and nursing. Not every old woman or even every enthusiastic young girl was fit for the work. It required training, intelligence, and assiduity. Indeed, the work was only second to that of the medical profession itself. Some critical prompter seems to have suggested to him that

Digitized by Google

nurses were apt to fancy that patients existed for the display of the importance of their art instead of regarding them as needing their consideration. And he gave this hint, which the best nurses will take in good part, with all his unfailing grace and good taste. The share of the medical profession in the work of hospitals was, of course, amply acknowledged by so careful an observer. The "patience, perseverance, and assiduity of the members of the noble profession had awakened the public conscience to the duty of seconding the efforts so nobly made by the profession." The Duke of Devonshire enlarged on the marvel of our voluntary hospital system, and maintained that, though involving great care and responsibility on the part of hospital authorities, and heavy indebtedness, it did not suffer in efficiency. He showed the indirect advantages which the public reaped from hospitals as places where professional education and skill were promoted. If there was any defect in his Grace's handling of this great subject it was in the absence of a word as to the abuse of hospitals, which discourages charity and promotes pauperism.

DEATH BY LIGHTNING.

THE effects of lightning as it passes to earth through the body of a man vary within an astonishingly wide range. It sometimes happens that a person is killed outright without any symptoms or sign of injury. It may be that death is preceded by collapse, paralysis, or convulsion, usually there are marks where the current has entered or left the body, or clothes may have been scorched, or hæmorrhages may have occurred, and more than one case has been recorded where boots have been torn off the feet and nails driven out of the soles of the boots. Seldom does it happen that lightning leaves such appalling evidence of its transit as that disclosed at an inquest held at Hulford House, near Guildford, on Saturday last. The evidence showed that on the previous Wednesday there had been a single flash of lightning and a clap of thunder, and about half an hour afterwards Major Jameson was found lying on his face in a field quite dead. Around him, in a radius of several yards, were his clothes and boots, which had been torn and scattered about in an extraordinary manner. The lightning appears to have struck him on the right side of the head, tearing his cap to pieces and burning his hair off. It then passed inside his collar down the front of his body and both legs into his boots, which were torn to pieces, and then passed into the ground, making a hole about eighteen inches in circumference and three inches deep. His collar was torn to pieces, the front of his shirt was rent into ribbons, the jacket and under-vest were literally torn to shreds, and the knickerbockers he was wearing were stripped from him and scattered on the ground. His stockings and gaiters were similarly torn in pieces, and on the boots the lightning had a remarkable effect. They were burst open, some of the brass eyelet-holes were torn out, nails were forced out, and the soles torn off. The skin had been torn off the chest, and the right leg was torn and blackened; blood was issuing from the mouth and right ear. In connexion with this fatality two circumstances of a more or less unusual kind may be noticed. There is, first, the single lightning flash, neither preceded nor followed by others in the neighbourhood; and secondly, the fact that the person who was struck was "in the open." The latter comparatively seldom happens, perhaps because shelter is instinctively and perhaps unwisely sought: Here there was no warning and no time for this, and so, without any neighbouring object at hand to subdivide and share the discharge, the latter had only one route to earth—viz., the body of its victim. The wet or dry condition of the clothes is an important point in such cases. It often happens that in persons exposed to a thunderstorm the clothes are wet, and therefore afford a comparatively easy passage to any electric current. In the case above detailed the clothes were presumably dry, and therefore bad electrical conductors, and the destructive effect of the lightning would be in proportion to the resistance encountered in transit.

"VESTRIES AND QUACK ADVERTISEMENTS."

IN THE LANCET of May 29th, 1897, we referred to this matter and quoted a letter from a correspondent on the subject. Our correspondent now writes: "In consequence of my further remonstrances with individual members of the vestry, together with your paragraph, the vestry gave fresh consideration to the matter, and a sub-committee was appointed to inquire into it. The sub-committee reported that the advertisement in question was an improper one for the vestry to exhibit, and in accordance therewith the vestry resolved that it should be removed. I am glad to say that this has been done, and the clock with the objectionable advertisement has disappeared." We are pleased to find that the action of our correspondent and our own protest have had the desired effect. The abuse of advertisements is becoming a serious matter. There is a place for everything, but public buildings in towns and fields bordering our railroads are emphatically not the places for the display of commercial enterprise.

DIET DURING COURSES OF MINERAL WATERS.

DR. F. PARKES WEBER, writing in a recent number of *Treatment* on the dietary suitable for patients at mineral water resorts, says that C. von Noorden, Karl Grube, and many others have pointed out that the true rules of diet to be observed whilst undergoing a course of mineral water are the rules suitable to the individual constitution of the patient and the complaint from which he is suffering. Amongst articles of diet which were supposed to be specially unsuitable at Carlsbad butter and fats were the most noteworthy because they are such extremely important foods. The mineral water was supposed to prevent their proper digestion and assimilation. Not only was fat prohibited with sulphated alkaline waters, such as that of Carlsbad, but with muriated waters, such as those of Kissingen and Homburg. Recently, however, F. Kraus has shown experimentally that a course of sulphated alkaline waters does not prevent the proper absorption and assimilation of the fat taken with other food; and C. Dapper had already proved the same to be the case in regard to courses of muriated waters, such as those of Kissingen and Homburg. Kraus gave considerable amounts of fatty food to patients suffering from complaints likely to be met with at Carlsbad, treating them at the same time with fair daily doses of Carlsbad (Mühlbrunnen) water, and he found that the percentage of the ingested fat which could be recovered again in the fæces of these patients was not unduly increased by the use of the mineral water. Dr. Parkes Weber hereupon remarks that a fatty diet gives rise to trouble in certain cases independently of spa treatment, and in such cases the diet whilst the patient is at the spa will have to be regulated. For instance, patients who suffer from obesity or from gastric dilatation due to fermentation of the contents of the stomach must have their diet regulated with respect to fatty and fat-producing foods. There is no doubt that the facility for regulation of diet at some spas, such as Carlsbad, has greatly helped in their reputation for the treatment of certain affections, especially diabetes and obesity. Spas where by a strict *à la carte* system of dining the carrying out of dietetic rules is made comparatively easy are likely to outstrip their rivals where a *table d'hôte* system

Digitized by Google

prevails. Moreover, the strict quantitative limitation of the evening meal must have had, and still does have, a wholesome effect at many health resorts. The patients can go to bed earlier after a light meal—a great advantage when they have to rise at a very early hour to drink the waters—and in most persons when free from excessive mental work the digestive powers are probably strongest during the middle of the day. In many persons, also, temporary discontinuance of strong tea or coffee in the morning can do no harm, and can best be carried out at health resorts during periods of rest from the mental work of ordinary life. The substitution of farinaceous soup, &c., which formerly constituted the morning meal at various spas, might still often be recommended.

THE INDIAN RISING.

THE rapid spread and extension of the rising among the tribal populations on the Indian frontier, especially at the present time, when India is only just emerging from a series of calamities of plague, pestilence, famine, and earthquake, is a grave business. The revolt of the tribes seems to have been quite unexpected by the Indian Government; and, notwithstanding that it has a large force in and about the frontier, the season is an unfortunate one for commencing military operations in a mountainous and very difficult country, and the transport and commissariat arrangements for such an expedition cannot be made without some necessary loss of time. Those who are opposed to the "forward policy" followed by the Indian Government will, of course, attribute the insurrection among the hill tribes to this cause, and probably with a certain measure of truth, but what has now to be done is to act and not to argue. The rising must meanwhile be put down, and the Khyber Pass and that of Kohat secured if we are not to lose military prestige and meet with further difficulties and disaffection. The task is an arduous and expensive one, but it has to be accomplished. An expedition at this season will, we fear, be attended with a good deal of inefficiency on account of sickness among the troops, and great demands will be made upon the military medical services in India. The strength and efficiency of the field hospital system of that country will be put to the test. We may add, however, that there is every reason to believe it is in a very different and improved condition to that which existed at the beginning of the last Afghan campaigns. Some difficulty will, we imagine, arise from the numerical strength of the medical departments being insufficient to cope with all the work that has to be performed in India at the present time. Malarious fever, often of a severe type, is usually prevalent in the Peshawar valley at this season, and cases of dysentery and enteric fever will almost certainly occur among the troops. Up to the present time the health of those taking part in the different expeditions is reported to be good.

TREATMENT OF PULMONARY TUBERCULOSIS.

FROM the time that Koch startled the medical world by the discovery of tuberculin numerous attempts have been made to purify this substance and so avoid the injurious effects produced by it. Hitherto these efforts have not met with success, although it is too early to speak definitely of Koch's new tuberculin. In the *Medical News* (New York) of July 3rd a most interesting paper appeared by Dr. J. O. Hirschfelder, of San Francisco, detailing certain experiments made by him. He proposed a theory that is certainly original. This theory was not evolved from the therapeutical results of his injections, but "the method of treatment was a consequence of the biological proposition." He drew attention to the successful results which had followed operations for tuberculous peritonitis, and stated his opinion that "it appears most probable that in these cases the entrance of air into the peritoneal cavity must have been the important factor; that an oxidation of the tuberculin present in the effusion was thus brought about; and that it was this oxytuberculin which effected the cure both of the local and of the general tuberculosis." Acting upon this hypothesis the problem of finding a method of oxidising the toxin without completely destroying it presented itself, and various methods of accomplishing this result were investigated. Dr. Hirschfelder found in the course of his experiments that the peroxide of hydrogen was the substance for which he was seeking. He then gave a detailed description of the preparation of his tuberculin and the method of oxidising it, and remarked that the greatest possible care was necessary in the preparation of this oxytuberculin, for if any appreciable quantity should escape oxidation fatal tuberculin poisoning might result from the large quantities which must be administered. The liquid when injected caused no greater local disturbance than any indifferent fluid would produce. There was no rise of temperature or any other unpleasant constitutional effect. Within a few days the cough and expectoration diminished, and the most striking effect was the rapid improvement in the appearance of the patient. He further went on to say: "The patients that have been treated by me with the oxytuberclin, those who came in the very early stage of the disease before cavities were present, have been rapidly cured ..... Patients in whom the disease was moderately advanced have likewise rapidly improved, and some have entirely recovered. Of the very advanced cases, many have shown marked improvement, and many patients that I have declined to treat as being too far advanced, but who pleaded so hard for the treatment that I could not refuse, have impressed me by the wonderful improvement they have shown." Tables were printed at the end of the paper giving the number of patients and the treatment at various stages of the disease, and the results as shown were certainly very satisfactory. We cannot comment further until more extended observations have been made, and meanwhile await with interest the results obtained by other physicians who may use oxytuberculin in the treatment of tuberculosis, pulmonary and otherwise.

SICILY AS A HEALTH RESORT

OUR Rome correspondent, under date Aug. 30th, writes:—"A mass of correspondence before me attests the impulse, as opportune as it is welcome, given by THE LANCET to Sicily's development as a health resort. The whole island, now that its advantages in point of climate, internal resource, and general attractiveness have received the *imprimatur* of medical science, seems to have realised the future that lies within its grasp, socially and economically, if only it follows up the indications and suggestions so clearly set forth. Take, for example, that lovely seaboard winding gently inland between Palermo and Cefalù—a marine exposure rich in attraction of every kind—and pause for a moment at the balneary station of Termini-Imerese. It is difficult to say whether the advantages of the place are more pronounced in summer or in winter—the former season admitting of *al fresco* bathing under the most favourable conditions and for a longer period than elsewhere; the latter with its supply of thermal waters only awaiting more effective utilisation than its 'Stabilimento microscopico' (as a correspondent playfully calls it) has hitherto vouchsafed. For Termini-Imerese possesses in a degree but partially shared by other thermal resorts in Italy, and hardly shared at all by its transalpine sisters, the advantage of being as available for the 'cura sudorifera' and for all-round balneary treatment during the winter months as during the summer. The opportunity, indeed, of combining escape from a northern winter

Digitized by Google

with the prosecution of a thermo-mineral 'cure' is one which many a British sufferer from gout or rheumatic arthritis would eagerly embrace, and Termini-Imerese presents this under every desirable condition, essential and accessory, except one, and that is the 'Stabilimento' itself. As already said, this establishment is on a very small—well-nigh Liliputian—scale, sufficient, possibly, for those who have hitherto frequented it, but quite unequal to the *clientèle* which nature and science clearly mark out for it. As a correspondent suggests, it has remained in this undeveloped condition because, between Cefalù and Solunto, it has always been absolutely without a rival, which is another way of saying that the balneary resources of that exceptionally favoured line of coast have had, like Sicily generally, to await such a demonstration as THE LANCET has been the first to give. But, as I now learn, it will not long be allowed this excuse for neglect of opportunity. The spirit of competition is awake and abroad, and in self-defence, if from no other motive, Termini-Imerese will have to 'march with the times' and add to its accommodation and appointments if it is not to be distanced by more enterprising neighbours. The requirements of civilisation—particularly of English-speaking civilisation—'che le attrattive del sito e le esigenze dei tempi reclamano a voce alta' (which the attractions of the situation and the conditions of the times so loudly demand) will have to be complied with; and then, but not till then, we shall see Termini-Imerese taking its proper place among less favoured rivals in counterpoising the 'Riviera Levante' and the 'Riviera Ponente' by a yet more to be recommended 'Riviera Siciliana.'"

CHOLERA IN THE DONGOLA EXPEDITIONARY FORCE, 1896.

WE may safely congratulate Brigade-Surgeon-Lieutenant-Colonel Gallwey not only upon his report,[1] but also upon the successful way in which he and the medical officers under him treated the cholera epidemic which so inconveniently hampered last year's military advance upon Dongola. Campaigning in the Soudan means warring against any dervishes who happen to be in that part of the desert, but it means much more—fighting against the elements of nature and getting gunboats through difficult cataracts during the few weeks of high Nile flood. Consequently the expedition had to continue its advance in spite of cholera, and the sanitary duties were necessarily subordinated to the hard work of the campaign. The infection reached Assouan by means of a native servant on June 8th; the first case in the Egyptian army occurred on June 12th and the last on Aug. 31st. The only time the disease became in the least virulent was from the end of June to the end of July, and the whole epidemic spread over 500 miles of river, road, and railway. Details are given of one healthy regiment which reached a cholera-infected barge on June 12th and developed cholera on the 14th; also a second regiment which arrived healthy on June 21st, while cholera broke out in it on the 23rd. We therefore fail to see why the writer in two places states that the incubation stage was usually seven or eight days. From the experience of three separate outbreaks he points out that the disease may be stamped out in six days in a military camp where early intelligence of the first case is received; where absolute control is possible, and where the water-supply can be efficiently protected from contamination. He is evidently a consistent believer that cholera is a water-borne disease, and though "it was not possible to boil drinking water for the troops protection of the supply formed the chief point in all camps." The regulations for barge traffic, for camp followers, and for native villagers were well planned and carried out, and included notification, isolation, disinfection of personal effects by boiling, and of dwelling places by disinfectants. The military cases numbered 403, with a death-rate of 58 per cent.; the civilians furnished 897 cases of cholera, with the higher death-rate of 82 per cent. It is satisfactory to note that in the Egyptian army of 16,000 men "not a single attendant on patients contracted the disease." Many of our readers will remember that Surgeon-Captain Trask, while on inspection duty, contracted cholera at Ferket on the morning of July 25th, and died the same afternoon.

[1] Cholera Report of Frontier Mudiria and Dongola Expeditionary Force, 1896; pp. 15.

DEATH OF DR. ALFRED HALL, OF BRIGHTON.

WE have to record the death on Aug. 30th of Dr. Alfred Hall, of 75, Lansdowne-place, Brighton. His work was long since done and his age was ripe; but his stately form, his genial face, and his kind heart were all in evidence till a very recent period—a fact which makes his removal still to seem premature. Dr. Hall attended as physician both the Founder of THE LANCET and his wife, and a link with the past of peculiar interest to ourselves is now broken. We hope next week to give more detailed notice of his life.

OXIDE OF IRON IN BACTERIA.

THE association of oxide of iron with certain bacteria has been remarked by various observers, and an instance of this phenomenon occurring on a large scale has been investigated by Professor Manabu Miyoshi, who holds the chair of botany in the University of Tokio in Japan. His observations are published in German, and appear in Vol. X. of the *Journal* of the College of Science, Imperial University, Japan. The material examined by him was a ferruginous mud from the hot springs of Ikao; it is formed upon stones and earth under the influence of the warm ferruginous water which trickles from crevices in the rocks, and on account of its therapeutic properties it is often collected by persons who go to the springs to bathe. This mud consists entirely of bacteria, and can be easily separated from the ferruginous matter which contains few or no bacteria, as it has a pale ochre-yellow colour, and a homogeneous, fibrous, slimy consistence, whereas the latter is of a dirty brown colour and a finely granular consistence. Microscopic examination proves that the mud consists entirely of bacteria cells. The smallest possible portion spread evenly on a cover-glass and dried over a spirit lamp shows innumerable yellow, thread-like cells of unequal length, varying from $\frac{1}{4}\mu$ to 1μ in diameter; they are both straight and curved, and they may be either solitary or grouped in masses. With these thread-like cells there are mingled a number of minute rod-shaped cells. The bacteria seem to resemble the *Leptothrix ochracea* of Kützing; further observations are necessary in order to determine whether they are a new species or not. When the cells are treated with moderately strong hydrochloric acid they not only lose their yellow colour but their outline disappears without leaving a trace behind, and the subsequent addition of ferrocyanide of potassium produces the blue colour characteristic of iron. If a much weaker acid is applied to one side of the preparation the cells become gradually decolourised, and ultimately there remain hyaline fragments of cells, which are seen with difficulty but become easily visible after staining with fuchsin solution. The action of hydrochloric acid led Professor Manabu Miyoshi to believe that the oxide of iron is not deposited on the walls of the cells, but is more or less intimately incorporated with them. The cell walls were entirely free from coarse granules, but on careful examination with Zeiss's $\frac{1}{12}$ immersion lens and No. 4 eyepiece he found extremely minute particles on many cells. In addition to the thread-like and rod-shaped cells the bacterial mass contained a small number of cells resembling

Digitized by Google

spirochæta (some of them similar to the *spirillum ferrugineum* of De Thoni), which were often associated in ramifying groups. No others of the more common iron-containing bacteria—such, for instance, as *crenothrix Kühniana* (Rabenhorst)—were found in this particular mud, but fragments of broad, thread-like cells, with diagonal walls, were sometimes seen, which were probably psichohormium; diatoms were also often observed in the less pure portions of the mud. On account of the minuteness of the bacteria cells it could not be determined whether they contained plasma or not. The natural conditions at these mineral springs are highly favourable to the growth of bacteria; the water contains 0·021 gramme of bicarbonate of iron per litre, and has a temperature varying from 41° to 45° C.

THE ISOLATION OF CONVALESCENTS FROM DIPHTHERIA.

IT is well known that diphtheria bacilli are sometimes to be found in the throats of patients long after recovery from the clinical symptoms of the disease is complete, and under such circumstances both these convalescents and their relatives may be very sceptical when informed that the risk of infection being communicated to others is not yet at an end. In a series of 605 cases of diphtheria the bacteriologists of the New York Health Department found that in 304 cases the bacilli disappeared within three days. In 301 cases they persisted for a longer time—viz., in 176 cases for seven days, in 64 cases for twelve days, in 36 cases for fifteen days, in 12 cases for three weeks, in 4 cases for four weeks, in 4 cases for five weeks, and in 2 cases for nine weeks. With reference to this subject the Department makes the following important statement: "The bacilli which, in a certain proportion of cases, persist in the throat after an attack of diphtheria, are always virulent for some time. In the exceptional cases in which the bacilli persist for a very long time it is found that they occasionally lose their virulence a few days before their final disappearance, while in other cases they retain their virulence to the end." The rule laid down by the Department in its circular of May 1st, 1896, is in the following terms: "Persons who have suffered from diphtheria should be kept isolated until cultures prove that the bacilli have disappeared from the throat. When cultures cannot be made, isolation should be continued for at least three weeks after the membrane is gone."

UNQUALIFIED ASSISTANTS AND DEATH CERTIFICATES.

WE have often remarked on the little effect that seems to be produced on certain practitioners and their unqualified assistants by the publication of offences under the Registration or Medical Acts, and of the grave penalties incurred thereby. One offender succeeds another protesting entire ignorance of the previous offences and their punishments. All the newspapers of London lately gave publicity to a case in Islington where an unqualified assistant who ought to have known better forged a certificate of death and was duly punished for it. Now in the very same parish the superintendent registrar exposes before the coroner another case where a poor woman took her child to the surgery of Mr. Day, 1, Benwell-road, N., the patient being prescribed for by Mr. Charles Day's son—Mr. Alfred Harry Day—who had assisted his father for twenty years, but had had no other medical education. He attended the child till death, and then gave a certificate in his father's name. In this case, as distinguished from the other, medical evidence was given by Mr. Jackson Clarke, who had made a post-mortem examination. He found catarrh of the stomach, and regarded the treatment as being usual in such cases, and the cause of death as natural. Of course, this does not dispose, as the coroner said, of questions that may be raised elsewhere. It was explained that the wife of Mr. Day, senior, had died, and that Mr. Day was absent from town in consequence. Everyone will sympathise with Mr. Day in this respect, but it is to be regretted that he did not make provision for having his patients seen by a registered *locum tenens*.

DEATH OF DR. BRAXTON HICKS.

THE death is announced of Dr. J. Braxton Hicks, F.R.S., who has been residing in Lymington, Hampshire, since his retirement from practice. Next week we hope to publish an extended notice of the career of this distinguished obstetrician.

ACUTE PNEUMOCOCCUS INFECTION.

DR. W. R. TOWNSEND describes in the *New York Polyclinic* an unusual case of bacterial infection, the patient being a girl, six years of age, who required to have a tenotomy performed and was consequently admitted to the Hospital for the Relief of the Ruptured and Crippled. At the time of admission she was otherwise in very good health, but a few days afterwards she suffered from abdominal pain and vomiting, her temperature at the same time rising to 104·2° F. Her throat was congested, but showed no exudation, and bacteriological examination yielded no result. She had a slight convulsion twenty-four hours after the commencement of the symptoms, and six hours later she died. A post-mortem examination was made fourteen hours after death, the appearances noted being as follows: The body was fairly well nourished. The brain was normal, but the pia mater was congested. Both lower lobes of the lungs were intensely congested and œdematous, the bronchi contained frothy mucus, and the lining membrane was reddened. The spleen was congested and soft. The kidneys were normal in size, their capsules were adherent in several places, the cortex was thickened, and the markings were very indistinct. Bacteriological examination showed a general pneumococcus infection complicated by a streptococcus infection of the blood of the lungs and heart. The brain contained pneumococci. The blood in the heart, the lower lobes of both lungs, the spleen, and both kidneys contained pneumococci and streptococci. The case is a highly interesting one and is moreover a notable example of the value of bacteriology in diagnosis.

THE EMPLOYMENT OF GLOVES IN SURGERY.

FOR some time past Dr. J. Mikulicz, who is Professor of Surgery in the Faculty of Medicine at Breslau, has been in the habit of wearing gloves while performing most of his operations, and especially when engaged in laparotomy. If, however, the intervention is connected with regions that are specially exposed to infection—such, for example, as the rectum, the urethra, or the buccal cavity—he does not cover his hands, holding that gloves under such circumstances could only favour contamination by helping to convey noxious germs from the diseased parts to those still remaining healthy. Unlike Dr. Zoge von Manteuffel, Dr. Mikulicz does not make use of india-rubber gloves, as he finds them embarrassing, but employs the ordinary thread article, which can be readily washed and sterilised under steam. All the assistants and attendants have to wear gloves like the surgeon, but as thread gloves are, of course, far from impermeable the wearers are required before putting them on to disinfect their hands by means of alcohol and corrosive sublimate. As a rule a single pair of gloves suffices for a short operation, but when the intervention is of longer duration two or

Digitized by Google

more pairs are used in succession. As an additional precaution Dr. Mikulicz likewise dons a muslin mask when about to operate; it is suspended from his calotte, and covers his nose, mouth, and beard in such a way that neither speech nor respiration is interfered with, while the wearer can even cough or sneeze without any risk to the patient. According to a French medical journal[1] Dr. Mikulicz has obtained very satisfactory results since he adopted the above-mentioned method of procedure. Formerly in his practice operation wounds used frequently to become infected, while suppuration round suture-points was of constant occurrence, but now these disheartening complications never by any chance show themselves. He consequently looks upon gloves as an unfailing remedy for the greatest defect of modern aseptic surgery, to wit, the insufficient disinfection of the hands of the operator. The above-quoted authority further states that Dr. Küstner, Professor of Obstetrics at Breslau, wears thread gloves in all his laparotomies, and that Professor Trendelenburg, of Leipzig, and his assistant, Dr. G. Perthes, both make use of long gloves of fine silk reaching to their elbows.

WE desire to express to the Postmaster-General of Canada our hearty thanks for the kind privileges accorded to us in connexion with the posting of our Special Canadian Supplement of THE LANCET throughout the Dominion. Owing to the liberality of his department the distribution of copies to the entire medical profession of Canada will be effected at a merely nominal cost.

SIR WILLIAM GOWERS, M.D. Lond., F.R.S., has been elected an honorary member of the Société des Médecins Russes de St. Petersbourg. This society is one of the oldest in Russia, dating from 1833, and almost the only one instituted in the reign of Nicholas I. The present president is Professor Popoff.

THE total contributions to the Prince of Wales's Hospital Fund for London up to September 1st (excluding the proceeds of the sale of the hospital stamps) amounted to £181,741 12*s.* 9*d.*

DR. THOMAS D. REED has been appointed to the Commission of the Peace for the district of Montreal, Canada. The commission was gazetted on July 24th last.

THE Sixth Report of the Royal Commission appointed to inquire into the subject of Vaccination, with minutes of evidence and appendices, was issued on Wednesday last.

WE are informed that the University of Cambridge was represented at the International Medical Congress at Moscow by Professor T. Clifford Allbutt.

Pharmacology and Therapeutics.

EFFECTS OF PYOGENIC MICROBES AND THEIR TOXINS.

DR. MOLODOVSKI publishes in the form of a Thesis for the St. Petersburg M.D. an account of a series of observations on the comparative effects in ophthalmic operations of infection with a pure culture of staphylococcus pyogenes aureus and with the toxin of this microbe. His experiments were conducted on rabbits, the wounds being infected with two days old cultures or with toxin obtained by filtration of cultures through a Chamberland's filter. In another set of experiments the toxin was introduced into the anterior chamber of an eye that had been operated upon to the amount of 0·2 cubic centimetre. Altogether sixty-five experiments were made. Twenty-four hours after the infection of a wound involving the cornea only, or the cornea and also the lens, by a culture, muco-purulent inflammation developed in the conjunctiva together with purulent iritis. A wound of a more serious nature naturally produced even more grave complications. Thus, when the lens was extracted without any loss of vitreous, infection with colonies of pyogenic cocci caused purulent inflammation of the iris and choroid, while if the extraction of the lens was accompanied by loss of vitreous the whole of the coats of the eye were involved—that is to say, panophthalmitis resulted. When the toxin was employed as the infective agent and the operation was confined to wounding the cornea and lens, simple catarrh of the conjunctiva with serous inflammation of the iris and ciliary body with hyperæmia of the anterior portion of the choroid resulted. When the lens was extracted with or without loss of vitreous the serous inflammation involved the choroid. All the wounds infected by the culture became purulent, but those infected with the toxin only healed by first intention. The development of inflammatory signs was slower in the case of cultures than in that of the toxin, but was of much longer duration, continuing indeed long after the toxin inflammation had ceased and the wound had cicatrised. When the toxin was introduced into the anterior chamber of an eye that had been operated on it was found that if the lens had only been incised the inflammation set up was not of a serious character, the lesion being cured generally in about a fortnight. If the lens had been extracted without loss of vitreous, capillary inflammation of the iris and ciliary body occurred, with the result in the majority of cases of loss of the eye from formation of connective tissue in the anterior chamber. When the extraction of the lens had been accompanied by loss of vitreous the result was in all cases fatal to the organ from development of connective tissue both in the anterior and in the posterior chamber. A somewhat similar series of 127 experiments has been made by Dr. Solovieff on the comparative effect of cultures of pyogenic microbes and the toxins produced by them on rabbits' eyes that had not been operated on. The conjunctival sac of the rabbit's eye appears to form an excellent culture medium for these organisms, and when a pure culture of the staphylococcus pyogenes aureus or of a pyogenic streptococcus is introduced into the sac some catarrh is produced, which, however, soon passes off. The toxin of the staphylococcus produces more effect—acute conjunctivitis lasting for one or two days—and the toxin of the streptococcus a still more acute form of inflammation with extravasations of blood in the conjunctiva. Both toxins also pass into the cornea, the former producing infiltration of that body together with serous inflammation of the iris, and the latter toxin causing inflammation of the cornea and capillary inflammation of the iris and ciliary body. Inoculation of the cornea either with one of the cultures or with one of the toxins sets up purulent keratitis with hypopyon and cyclitis. Introduction of one of the cultures into the interior chamber produces purulent inflammation of the whole of the coats of the eye with ultimate atrophy of the organ. When the toxins are introduced into the anterior chamber the same results are obtained as when they are used to inoculate the cornea. When the cocci are introduced directly into the posterior chamber violent inflammation is at once set up which destroys the organ. The toxins introduced into the posterior chamber produce the same effects on the deep structures of the eye as are observed when the cultures are introduced into the anterior chamber. Neither the microbes nor their toxins when introduced into the vitreous humour appear to penetrate into the substance of the brain or even into the optic nerve, owing probably to the closing of the lymphatic canals by the violence of the inflammatory process, so that however serious their presence may be for the eye there does not seem to be much danger to life in such cases by extension of the inflammation to the cerebral membranes or to the brain itself.

NOTE UPON THE TOXIC EFFECTS OF THE SWEAT OF A HEALTHY MAN.[1]

BY S. ARLOING.

I.

THE toxic character of sweat eliminated in the course of an infectious disease ("*d'une infection*") is generally admitted at the present day; but that of sweat from a

[1] Translated from Comptes Rendus, vol. cxxv., No. 4, July 26th, 1897, p. 218.

Digitized by Google

healthy man is much disputed, notwithstanding that the older physicians attributed to the secretion of the sudoriparous glands a definitely depurative action. This question can only be put to the test by injecting into the blood of animals suitably chosen sweat secreted by healthy human subjects. In consequence probably of the difficulty encountered in procuring the reagent the question has been attacked by very few experimenters. So far as I am aware Röhrig and Queirolo alone have experimented with injections of sweat. The first named, who made only a single injection upon a rabbit, came to the conclusion that the effect was toxic; the second, who made fourteen injections, thinks that the sweat of healthy persons does not eliminate any toxic substance. I have thought it necessary to renew the study of this subject, and have obtained the elements of sweat by divers processes and many specimens of normal sweat, thanks to the coöperation of M. Berthe and Dr. Sonrel. The experiments have accordingly been very various. From all these experiments I have come definitely to the conclusion that toxic matters are present in the sweat of a healthy man. Injected into the blood sweat causes the death of a dog following upon an average dose of 15 c.c. per kilogramme of the living animal; of a rabbit with a dose of 25 c.c. after an interval of from twenty-four to sixty-two hours. It will also kill a guinea-pig if introduced in a sufficient dose subcutaneously into the peritoneum or the connective tissue. Although I have not yet produced immediate death, the injections always occasion an illness of a certain duration. The duration of the illness, the gravity of the symptoms, and the dose necessary to cause death vary with the conditions under which the sudoriparous glands have performed their functions. For instance, sweat secreted under violent muscular exertion possesses a toxic efficacy exceeding by one-fourth or even by one-third part the ordinary toxicity. Furthermore, other things being equal, sweat obtained by artificial sudorific means exhibits a minimum of toxicity.[2]

The toxicity of normal sweat being established, I proceeded to ascertain the nature of the poisoning, and take for illustration the troubles experienced by a dog. As a general rule the introduction into the jugular vein of the first quantities of sweat occasions a lively excitement, quickly followed by a remarkable sedative effect, which continues throughout the course of the injections. The dog is thrown into a state of the most complete calm, the eyelids are half-closed, under the influence as might be supposed of a narcotic; but it is nothing of the kind, for the dog briskly regains its feet if set at liberty. Very soon it becomes profoundly miserable. The principal muscles are attacked by tremblings. The eyes are tearful. At this stage the temperature is notably elevated, and it may be observed that the dog is attacked by disorders of the digestive system, such as repeated vomitings, at first alimentary, afterwards bilious; abdominal pains; diarrhœic stools; strainings (*épreintes*), and sometimes slight intestinal hæmorrhages. The breathing is short and rapid. The beating of the heart, much accelerated at first, resumes after some hours its ordinary rhythm; then it becomes accelerated afresh and gradually feebler. The arteries are soft and compressible and the pulse is barely perceptible. The extremities become cold, the animal grows indifferent to its surroundings, its prostration becomes extreme, its temperature falls below the normal, and finally it succumbs after having exhibited a series of symptoms which strikingly recall those that follow upon the administration of certain microbic toxins. When the poison does not assume this aggravated form the malady lasts for several days. The animals manifest an improvement at the end of four-and-twenty hours—a transient improvement, followed by a moderate degree of fever, loss of appetite, profound exhaustion, and sometimes a loss of power in the members bordering on paralysis. In this case, as in the preceding, the subject succumbs with subnormal temperature. If the dose of sweat injected is less strong or the subject more resisting two results may follow: the animal may recover completely or it may fall into a cachectic condition which carries it off in the space of from fifteen to thirty days.

Having thus given a summary account of sweat poisoning I propose to give details of some of the principal disturbances. In this note I will deal with the troubles arising to the circulation which I have studied minutely with the aid of the graphic method. When first introduced into the blood the sweat produces disturbances of which the intensity varies with the degree of toxicity or of concentration. They are exhibited from ten to twenty seconds after the commencement of the injection. Amid manifestations of excitement, cries, and complaints, the pulse suddenly becomes small and accelerated; from 120 pulsations a minute it mounts to 240 and 300; simultaneously the arterial pressure rises and attains sometimes 200 mm., then rapidly falls to about 70 mm. Considering the rapid descent of the curve and the smallness of the pulse one begins to fear for the life of the subject, and this the more since these symptoms usually coincide with irregular and superficial respiration. With certain animals and certain kinds of sweat these troubles are less acute, and being more moderate they are more easy to observe. They are least when the sweat employed is a secretion obtained artificially after long repose. This crisis is feeble or absent after subsequent injections. The crisis over, the pressure gradually falls and reaches a point below the initial pressure; the heart becomes calm and beats with greater energy, so that after an hour or an hour and a half the circulation is no longer disturbed in proportion to the gravity of the situation. But if the animal be left to itself for eight or ten hours, and then the arterial system be again examined by means of graphic apparatus, a considerable fall of arterial pressure and acceleration and enfeeblement of the pulse will be detected. Thus, in one experiment before injection the pressure amounted to 176 mm. of mercury and the pulse was 96. One and a half hours after the injection of the poison the pressure had fallen to 160 mm. and the pulse had gone up to 120. Nine hours later the pressure was 110 mm. and the pulse 156. This noticeable change in the pressure, pulse, and heart coincides with the phase of prostration and with the establishment of an abundant sero-sanguineous exudation (*exhalation séro-sanguinolente*) upon the gastro-intestinal mucous membrane rather than with any general phenomenon of vaso-motor dilatation. I have observed that at the moment of most severe distress in the circulatory system, when the pulse is most accelerated, the excitability of the moderating nerves of the heart remains intact. The sudoral poison therefore acts chiefly upon heart exciting centres and the muscular fibre of the heart.

In a subsequent note I propose to examine the disturbance occasioned to other important functions.

IMMORALITY AMONG SCHOOL BOYS.

BY MAURICE C. HIME, M.A., LL.D.,
SOMETIME HEAD MASTER OF FOYLE COLLEGE, LONDONDERRY.

I RECEIVED so many letters concerning the special form of immorality indicated in the above heading from readers of THE LANCET since the appearance of a letter signed "Father" in its columns,[1] that it seems to me to be of sufficient general interest to justify me in asking for space wherein to express the result of my thirty years' experience as a head master in regard to this vice at somewhat greater length than I could conveniently adopt in a letter to each of my several correspondents.

I will speak, first, of the prevalence of the vice in boys' schools; next, of the duty of headmasters regarding it; thirdly, of the best means of preventing and checking it; and I will conclude with a few words of encouragement to the educator, whether schoolmaster or father, who strenuously exerts himself, with the help of God, to safeguard the boys entrusted to his charge from the sin in question.

That the vice exists, to a greater or less degree, wherever many boys are gathered together under one roof, who with any knowledge of boys will deny? Some schoolmasters have spoken to their pupils on the subject; others have written pamphlets about it for private circulation; others have urged fathers to caution their sons concerning it before sending them to school; purity societies have issued leaflets that can be purchased at their offices; and medical men have published books, numerous and important, on its cause and cure. And yet, the above facts notwithstanding, hundreds of head masters go on year after year as if blind to this truth,

[1] THE LANCET, June 12th, 1897, p. 1649.

Digitized by Google

ignorant or affecting to be ignorant of it. It is so painful to believe. As well expect a neglected garden to be free from weeds as a school managed by one of these "blind guides" to be free from this vice. How absurd to suppose that the devil, who forced his way into Paradise, will not force his way also into boys' schools, most of all into those schools the head masters of which "having eyes see not, having ears hear not, neither do they understand"!

The prevalence of this vice in most boys' schools may accordingly be taken for granted. This then being so, it follows that every professional educator is plainly bound by the duties attaching to his office to endeavour by all means in his power to defend his pupils, and help them to defend themselves, from this and every other pollution. Educator I say, rather than schoolmaster; for a schoolmaster's duty is far more, be it noted, than merely to instruct his pupils in classics, mathematics, and the other school subjects. "Oh, but let fathers warn their sons of the prevalence and deadly nature of this vice before sending them to school. It is their duty to do so." Undoubtedly, it would be satisfactory if fathers were to forewarn their sons of the terrible temptations and dangers awaiting them at school, showing them how these temptations may be best resisted, and pointing out to them the fearful consequences of yielding to them. As a general rule, however, boys are not forewarned on the subject, as schoolmasters are only too well aware. Are schoolmasters, therefore, themselves to neglect warning them because their fathers have done so? Is A to shirk his duty because B shirks his? Furthermore, there are some boys whose fathers are dead; others whose fathers are dull, coarse, and indifferent, not caring a straw how their sons conduct themselves at school; others whose fathers are themselves sensualists of the commonest type; others whose fathers are so particularly fastidious, so hyper-sensitive, as to be unable, or at least unwilling, to speak to their sons on such an unsavoury subject. And what of the sons of such parents as any of the above? In short, it is all nonsense a schoolmaster's trying to evade his own obvious duty and impose it on someone else. By his own voluntary undertaking, of his own freewill and accord, the schoolmaster professes to develop the religious and moral as well as the intellectual faculties of his pupils, for the performance of which duty he receives, not only fees from their parents, but also in many cases an endowment, as headmaster of the school, as well. The schoolmaster who does not faithfully discharge this his manifest duty is indubitably an unfaithful steward, and utterly unworthy of the noble, self-sought name of educator.

As to the best means of preventing and checking this vice opinions will differ. The following I personally have found effectual. I will divide them into A, school arrangement; and B, moral suasion.

A.—1. Cubicles I would have none of. The dormitories in Foyle College had been fitted up with cubicles shortly before my appointment as headmaster, but I insisted on their being removed before I undertook the duties of my office. Cubicles I regard as mere inventions of Satan the better to enable boys, weak-minded or sensually disposed, secretly to indulge in odious habits. Cubicles are, besides, productive of increased dust, dirt, gloominess, disagreeable smells, and defective ventilation. Well ventilated, airy dormitories, with rows of beds, not too close, that can be all seen at a glance by the superintending master, with a master's bedroom at opening of each dormitory, were an essential part of my system; besides, the manly and good boys, who are always in a considerable majority in every well-regulated school, render in such dormitories the practice of this vice well-nigh impossible. Such odiousness would not be tolerated by them for a moment. But where there are cubicles it can, obviously, go on with impunity, unchecked, in secret, no matter how excellent the tone of the school may be. 2. Lying in bed in the morning—"soaking," as the boys express it—was discountenanced in every way. At a certain hour every morning the bell for getting up rang, and the moment it rang it was the duty of the master in charge to oblige the boys to get up—on Sundays and holidays just as promptly as on working days. The prolonged enjoyment of luxurious sloth is apt to demoralise even the best-disposed. 3. A sufficiently large staff of masters to enable me to have one or another of them always on duty during play hours was another essential part of my system. The companionship of a suitable master was always agreeable to the boys. He helped them with their games, prohibited loafing, bullying, filthy conversation, profane language, and other juvenile misdemeanours, while his very presence made smoking an impossibility. On the injury done to the growing brain and growing body of a little boy by the use of tobacco I need not dwell, neither need I dwell upon the sneaking, underhandedness, falsehoods, deceptions, misspending of pocket money, with the common results of such mis-expenditure, inseparable from indulgence at school in the forbidden weed. 4. Intimacies between older and younger boys were discouraged. I seldom or never observed such a friendship springing up without suspecting that, in all probability, the younger boy was being injured by the older one—instructed or misinstructed in forbidden things, rendered conceited, spoilt for companions of his own age, and so forth. 5. The letting out of boys during school-hours "for a minute," as the request to go out is generally worded, was reduced to a system. Only one boy was let out at a time, and on one master, and that my principal master, devolved the duty of giving or refusing, according to his discretion, the asked-for permission. The boy was expected not to remain outside for more than three or four minutes at the very most. Going out during school-hours was, in short, a good deal discountenanced. Boys were trained to expect that they would generally be required to remain in the schoolroom for as long, say, as a two hours' railway journey, or an ordinary Sunday morning church service. Think of the iniquities that have been transacted by boys in privies at schools where little or no vigilance was exercised by those in authority in regard to the number and the characters of the boys let out at once, or the length of time that they might stay out! The card playing, drinking, shameful bullying, and beastliness of every kind! I speak now from my own personal experience as a boy, and that in more than one school. The longest continuous period of class instruction—three hours—I broke up in the middle by permitting, or rather compelling, every boy then to leave the school for ten minutes' relaxation, during which period the doors and windows were all opened wide for ventilation purposes. Concerning the conduct of the boys during these ten minutes I entertained no misgivings. There is safety in a multitude, and all the more so when the great mass of the multitude is right-minded and well-disposed. When the great mass of the boys in a school is not right-minded and well-disposed there must be something strangely amiss in the head master; he would certainly not appear to me to be the right man in the right place. 6. Occupation of some sort, whether in the playfield or, on a wet day, in or about the school, was insisted on. Out-door games were obligatory on all boys except those forbidden them by a medical man—an exceedingly small, but usually most troublesome, minority. Where out-door games are not compulsory there there will be loafing. Where there is loafing, there impure thoughts—if not filthy acts and filthy talking—will be indulged in. The letting off of superfluous energy by means of out-door games—long walks being substituted for these games on Sundays—contributes much to the suppression of the lusts of the flesh in boy and man alike. "That Satan finds," &c., is a proverb that, where schoolboys are concerned, contains so much solemn truth that one wonders how it is that any schoolmaster can ever endure to see his boys loafing about unoccupied. "Work or play," "Labour or refreshment," should be the motto of every school. Boys thus incessantly occupied have no time for impurity, no desire for impurity—none, at least, compared with that pervading the hearts of the unemployed. 7. Reading during play hours was not allowed. The reading of fiction, except such fiction as the boys' mothers or sisters might safely read, was not allowed at any time. The mischief done to boys by the reading of highly sensational immoral literature is incalculable. 8. There was a rule in my prospectus that "The trousers must have no pockets in them." To see boys sitting or slouching about continually fumbling with their hands in their trousers' pockets or, only a degree worse, between their trousers and their skin or shirt, was more than I could endure with unruffled temper. The objections to the habit are obvious; it is dirty, disgusting, loathsome, ungainly. So far for the school arrangements. And, with much respect, I would like to add that, quite apart from their special bearing on the vice treated of, these arrangements will not be found unprofitable in any school.

B.—As to the moral suasion method, I on one occasion seriously addressed the boys when all specially assembled together, concerning this secret, unmentionable sin. I spoke

Digitized by Google

to them at once so pointedly that the guilty boys all quickly understood what I was speaking about, yet so generally that none of the others did. They only knew that I was speaking about something awful, and that the less thought or spoken about it the better. I explained to them how that a vice to which some misguided boys were addicted was (α) a sin—impurity of every kind, the impure thought and look as well as the impure act, being forbidden by Jesus; (β) unnatural—the best part of our nature, conscience, being utterly opposed to it, as was also self-love; and (γ) followed, if persisted in, by the most injurious, sometimes even fatal, physical consequences, such as irritability of the entire nervous system; debility, general or local; injury, irremediable to the sexual organs; overmastering, lustful desire; impotency; insomnia; insanity; idiotcy—although these consequences may be sometimes slow in overtaking the sinner; that, further, the utter deterioration of one's spiritual and moral natures also resulted from indulgence in this sin, sin thus leading on to more and ever more sin. On each of these points I dwelt at some length so as to make them, one and all, perfectly clear to those especially addressed. I, further, explained to them that we schoolmasters were not slow in recognising those guilty of this pernicious self-indulgence; that reverie at class, dislike to out-door games, moping, defective memory, a disinclination to look at one straight in the face, usually mark out these self-polluters. I implored of them to pray to their Heavenly Father, with all the sincerity of which they were capable, and that not once only but every morning and every evening of their lives, that the meditations of their heart, the words of their mouth, and all their acts might be always acceptable in His sight. I entreated of them to take the pledge, as it were, against this accursed sin—a sin so destructive of soul and mind and body alike. I begged of them to busy themselves always with some lawful, innocent occupation, an idle brain being, as they themselves knew, so abundantly prolific of evil thoughts. And, finally, I explained to them what efforts my masters and I were making so as to render it the more easy for them to eschew the terrible evil, telling them the meaning of the different school arrangements that had been made with this object in view, and beseeching them to fall in with these arrangements in the same spirit as that which prompted me in making them, for that I felt sure that, with my boys on my side, Satan could be effectually resisted, but that without their willing assistance my efforts must be, to a great extent, in vain. The boys listened to my address with breathless attention, all of them, with the exception of a few little boys who were evidently innocent of the sin, and did not understand to what exactly I was referring. Boys, I have generally found, not only listen attentively to such warning, but are most grateful for it. Many of them have indulged in the vice without fully realising its exceeding sinfulness, or being in the least aware of the evil consequences, especially as these are so often slow in manifesting themselves. Even when, as sometimes happens, the evil consequences do quickly overtake one guilty of this sin, they are frequently misunderstood, and often assigned to a totally wrong cause.

Such was the tenor and gist of my general address, but my efforts did not end here. To new boys coming subsequently to the college I spoke separately on the same lines, more or less distinctly according to the sort of boy each was and his age. Even the youngest and most innocent boy, I felt, could not but be benefited by being warned generally of the possible temptations awaiting him; of the best means of avoiding and resisting them; and of the injurious effects of sinful self-indulgence of every kind. "But is it not possible that such plain-speaking may do actual harm to the innocent boy?" No; good advice, given at once wisely and affectionately by an experienced and discreet schoolmaster, cannot, I venture to reply, do harm to any boy, good, bad, or indifferent—least of all to the first-named, the innocent boy, who had grown up to boy's estate without, we are supposing, ever dreaming or hearing of this abominable sin. At all events, I, personally, cannot recall any instance of a boy being injured by such warning; whereas I have known numerous instances of boys being immensely benefited by it. The greatest good of the greatest number is, in any case, the object at which we all should aim; and, obviously, there is no way of dealing with this, or any other prevalent sin, at which someone might not be found to cavil. And one thing is clear—this even objectors to the system herein recommended will themselves admit—that, whatever the best course to be adopted in dealing with this abominable practice may be, the usual silent system, the ignoring of the vice as though it did not exist at all, has been the source to mankind of infinite mental and bodily suffering.

Expulsion of the boy reasonably suspected, or actually detected, is the plan adopted by some schoolmasters—an absurd, injurious, and most unfair plan in my opinion. For in the first place the expelled boy may have been by no means the worst or single offender in the school; and accordingly the only effect of the expulsion may be, (*a*) so far as he is concerned, to mar materially his prospects in life, while of his odious self-indulgence he may not be in the least degree cured; and, (*b*) so far as the other boys are concerned, those not detected, to induce them to go on in their sinful ways, only more secretly than ever. For so long as even one boy in a school practises the vice, it is likely to spread. And how much more likely in a school the head master of which is satisfied to believe that the expulsion of a boy and the purifying of his school mean one and the same thing, and that with the expulsion his efforts after purity may be securely relaxed. Bad weeds grow apace, and a single diseased sheep may taint a flock of thousands. In the next place, the expelled boy or boys may be, in reality, the cleverest in the school, and even, only for their indulgence in this accursed practice, the most promising. Thus the school may have in reality lost rather than gained by the expulsion—expulsion for the contracting of an evil habit of which, wretched boys, perhaps they never heard until they went to the very school from which they are now turned out as outcasts! Moreover, it was assuredly to heal those that were sick—a fact apparently forgotten by these expelling schoolmasters—to call sinners to repentance, that Jesus came. What right, then, has a schoolmaster to attempt to wash his hands of the anxiety and trouble inseparable from his profession, properly understood? What right has he to pretend to retain as pupils in his school those boys only who in his opinion—an opinion for which there is rarely any sure foundation—"need no repentance"? A boy once desired to speak to me privately in my study. In real tribulation he assured me that since he came to the school, some months previously, he had never committed the sin of which I spoke to him on his arrival, but that every night he had most disturbing dreams—a doctor can guess all the rest of his admissions—and that he felt very ill, and thought he had better come and tell me; and that he hoped I would not expel him. "Expel you, my poor boy!" I said, "No, God help you! You have already, surely, been visited with sufficiently severe punishment—the punishment that has naturally followed your sinful conduct. I will call in the school physician, and we will see what can be done to relieve your sore sufferings and trouble." The outcome of the interview, briefly, was this: after the lapse of some months, this boy, almost quite recovered from his alarming infirmity, was one of the best behaved and most generally popular boys in the school—thoroughly trustworthy, first-rate at games, attentive at class, and diligent during preparation hours.

It should be a great encouragement to the schoolmaster, who leaves no stone unturned to eradicate this vice from his school, to remember that it is not boys only whom he his safeguarding against mental and bodily pollution, but men also. And what a scourge to themselves and to others impure men are! The purer the boy the purer the man. Similarly, the more impure the boy the more impure the man. Habit is a second nature. The boy who unwarned, undetected, uncensured, has secretly practised this abominable vice for years and years together, and so stimulated, unnaturally, the lusts of his flesh, is just the person, when he becomes a man, to yield to every temptation to gratify these lusts; that is, assuming that he has not damaged beyond cure his virile powers by the self-abuse he indulged in as a boy. "What is the harm of sexual gratification?" the youth who has deadened his conscience by self-abuse at school is likely to ask himself: "I never was told it was either sinful or injurious all the time I was at school." The undisciplined, ill-trained youth thus begins life at an immense disadvantage, caused by the supineness and blindness of his schoolmaster, whose bounden duty it unquestionably was to have explained to him the sinful nature and destructive effects of this vice. The boy, on the other hand, who has been accustomed to keep his passions under due control, and enters life, whether the university or a bigger world still, with a sound mind in a sound body, innocent, yet properly instructed as to the unnaturalness, the sinfulness, and the pernicious consequences, slow but sure, of this deadly sin,

Digitized by Google

is likely, if anyone is, to keep his body, when he becomes a man, in temperance, soberness, and chastity unto his life's end.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Sunderland Urban District.—Sunderland has a notoriety for enteric fever, and it is to this subject that Dr. Harold Scurfield devotes considerable space in his annual report. During 1896 there were but two of the thirty-three great towns that had a higher death-rate from enteric fever than had Sunderland. Wolverhampton heads the list with a death-rate of 0·41 per 1000. Bolton follows with a rate of 0·39, and Sunderland with one of 0·37. In, too, the matter of diarrhœa Sunderland is in bad company, but its rate in this respect is exceeded by Wolverhampton, Leicester, Salford, Birmingham, Liverpool, Preston, Bolton, Sheffield, and Hull. It appears that the excessive incidence of enteric fever in Sunderland began to manifest itself about 1889, and after a sudden drop in the wet cold summer of 1894 it reached the highest rate yet recorded in 1895, but in this year it has to be noted that a considerable amount of the increase was due to a milk epidemic. Dr. Scurfield finds that, taking the average rates for diarrhœa and enteric fever since the year 1888, the greatest number of deaths from the former disease occur in the thirty-fourth week of the year, while for enteric fever the maximum figure is reached in the thirty-sixth week; and in a very interesting special report which he has presented to the sanitary authority of his district Dr. Scurfield shows that during 1890–95 enteric fever was more prevalent in towns in which privy-middens largely obtained than in towns where the excrement was removed by means of water carriage, and on examining the figures for 1896 he finds that the same rule holds good. "Privy-midden towns" are regarded as those in which the number of privy-middens approximates or exceeds 5 per cent. of the population. Dr. Scurfield observes that the bacillus of enteric fever, being capable of resisting frost, can, when thrown on to a privy, live in the soil throughout the winter, and propagate itself when the ground gets hot in the ensuing summer, and he furnishes in his report instances where probably this phenomenon has occurred and where certain houses and even streets have become again and again invaded by enteric fever. Although the privies are nominally disinfected it is obvious, as Dr. Scurfield observes, that the chances of really destroying all the infection which may lie in the surrounding soil are remote in the extreme. To sum up, Dr. Scurfield urges that the privies are largely responsible for the enteric fever of Sunderland for the following reasons: *Negatively*, there is no reason to suspect the water-supply, the milk supply (save for a certain period of 1895), or the sewers as cause. *Positively*, it is found that enteric fever is more prevalent in privy-midden towns than in water-closet towns, and in towns where both systems of excrement disposal are in use the chief incidence of enteric fever is found in the houses and districts provided with privy-middens. Furthermore, certain houses and streets in Sunderland where the privy-midden system is in vogue have been frequently re-invaded by the disease. It is interesting to note in reference to the relation of prevalence and type of enteric fever in Sunderland that during 1895 there were 840 cases, with a fatality rate of 15·4 per cent., while in 1896 the 260 cases yielded a fatality rate of 20·8 per cent. As a sort of sequel to Dr. Scurfield's interesting report he and the borough engineer have made an estimate of the saving to the cleansing department of the borough which will accrue from the general adoption of the water-carriage system in Sunderland.

St. Helens Urban District.—Dr. John Robertson has recently made some very interesting and instructive observations upon the behaviour of enteric fever, and a notice of them may appropriately follow that of Dr. Scurfield's report, which we have just considered. As in the case of Sunderland, the notifications of enteric fever in St. Helens during 1896 were relatively small, while the deaths were relatively large in number. Dr. Robertson has calculated from the weekly returns from certain large towns which are sent to the Local Government Board the sickness rates from enteric fever per 1000 of the population in the thirty-one towns in question. It seems that in the matter of sickness incidence St. Helens, with a rate of no less than 2·07 per 1000, easily takes the lead, the next highest being Sheffield, with one of 1·81 per 1000. The lowest rate is that of Plymouth, 0·31 per 1000. As regards the seasonal prevalence of the disease at St. Helens a chart is given in the report before us which shows the weekly number of cases in relation to the temperature of the soil at a depth of four feet and of the air. Dr. Robertson has now furnished these charts in his reports for some years, and they show a distinct relationship in point of time between the prevalence of enteric fever and the temperature of the earth at a depth of four feet. Allowing a period of three weeks as a reasonable average time between the ingestion of the poison and the notification of the disease, it is found that from 1892 to 1896 inclusive enteric fever became prevalent in St. Helens three weeks after the soil temperature at four feet had risen to 52° F. Conversely, three weeks after the soil temperature fell below 52° a rapid diminution of cases took place. The experiments to which we have already referred were as follows, and their object was to ascertain if the soil of St. Helens offered a suitable nidus for the growth of the enteric fever bacillus. In order to ascertain this point three patches of soil—apparently *in situ*—were liberally sown with a diluted broth culture of enteric fever organisms, and later three other patches were similarly sown. The organisms grew and flourished during June, July, and August, while the weather was dry and there was abundant sunshine. Similarly during September and October, when the weather was wet and dull, the organisms were still plentiful. In addition to these experiments other patches of soil were sown at a depth of from nine to eighteen inches below the surface, and, what is a most interesting and instructive point, it was found that in every instance the organism had grown to the surface within two months. Again, another most suggestive point, it was found that in the case of all the samples by Nov. 20th the organisms could no longer be detected in the specimens of soil in which they were sown. As Dr. Robertson points out, it is by no means improbable that during the summer (the present time), when the temperature of the soil is favourable to the growth of the organism, its presence will again be discovered, and thus there may be furnished an object lesson of the manner in which enteric fever may disappear from a locality in the winter and re-appear with the heat of the following summer; in a word, Dr. Robertson considers that the soil pollution of St. Helens is a most potent cause of enteric fever in that place, and he furnishes statistics in support of that view. Dr. Robertson has also made some investigations to ascertain whether the degree of bacterial activity going on in the soil held any relation to the prevalence of enteric fever, and the amount of carbonic acid was taken as a measure of such activity. These observations are being extended, as also, it seems, are others in connexion with the height of the ground water in relation to the prevalence of enteric fever. The value of the serum diagnosis of enteric fever is spoken of very highly by Dr. Robertson, and he furnishes many instances in his report where this test cleared up existing doubts. The blood of forty-six persons was examined, and the conclusions are set forth in five groups. Group 1. Blood from persons in good health, who had never suffered from enteric fever. Results negative in every case. Group 2. Persons in good health, but who had, one to thirteen years previously, suffered from enteric fever. All of these—with the exception of one man who had gone through a typical attack of the disease a year previously—gave a definite reaction. Group 3. Patients suffering from diseases which were definitely not enteric fever. All save one case gave negative results; and this case, although the first test gave a positive result, subsequently yielded negative results, so that Dr. Robertson thinks there may have been an error in the test. Group 4. Patients suffering from undoubted attacks of typhoid fever. Nine cases were examined, and in each one a well-marked reaction was obtained. Group 5. This was the most important group, as it contained all the doubtful cases. Of 21 cases 10 gave a positive and 11 a negative result, and in each of the negative cases the result was proved correct by the subsequent history.

Durham County District.—Dr. Eustace Hill finds that in the annual reports of the district medical officers of health proper corrections are not always made in respect to the

Digitized by Google

inhabitants of the district who die outside the district, although it seems that, as a very general rule, "foreigners" who die within the district are rigorously excluded. The general death-rate of the county during 1896 was 17·5 per 1000, the rate for the six boroughs being 16 3 per 1000, and for the other urban districts 18·4 per 1000. Dr. Hill attributes the lower borough rates to better sanitary administration, and it is a noteworthy fact that the enteric fever death-rate in the non-county boroughs was materially below those of the other districts in the county. In deploring the absence of uniformity in the matter of notification of disease Dr. Hill observes that the cost of administering the Notification Act can hardly be adduced as a reasonable excuse for its non-adoption, seeing that the cost in the administrative county during 1896 was but £1 3*s.* 6*d.* per 1000 of population. There was a marked decrease in the prevalence of enteric fever throughout the county during 1896, but there was a slight increase in the fatality rate. The largest number of cases was notified during August, while in former years the maximum has occurred in September or October. At Jarrow and Houghton-le-Spring certain cases of enteric fever were regarded by the district medical officer of health as having possibly been caused by shell-fish. Dr. Hill thinks that little good results under existing circumstances from the notifications of puerperal fever, since no supervision seems to be exercised by the officers of the local authority in the county. Surely some preventive measures should be taken in cases of this kind. As regards isolation, there are still nine urban and six rural districts which are as yet unprovided with isolation hospital accommodation. There are several schemes in hand for the improvement of the water-supply of the county, and the Local Government Board has refused to sanction the application of the Bishop Auckland Urban District Council to borrow money for taking water from the River Wear after it has received the unfiltered sewage of a population numbering several thousands. The Durham County Council opposed the application, and it is clearly a matter for congratulation that they were successful. The condition of the River Tees above the Darlington intake has, we are glad to hear, been considerably improved, much of the sewage of Barnard Castle having been diverted, and schemes are in progress for still further reducing the pollution of the river from the Durham side. The Yorkshire villages are, however, it seems, still contributing their sewage. The County Council took action in certain instances last year, under the Housing of the Working Classes Act, in cases where the local authority had neglected its duty. Dr. Hill again insists that the excessive prevalence of enteric fever and diarrhœa in the county is in large part due to the pollution of the subsoil around dwellings by the percolation from privy-middens. If, he points out, the model by-laws of the Local Government Board were adopted and enforced throughout the country the objectionable ashpit privies could no longer be erected.

Cheshire County District.—The population of the administrative county is estimated for 1896 at 536,644. The birth-rate of the population was 28·5 per 1000, the rates ranging from over 38 per 1000 to 14·8 per 1000. The general death-rate of the district was 15·6 per 1000, the rates ranging from 23·4 to 8·2 per 1000. The infantile mortality in the district was markedly lower than in 1896, but in one district—that of Mottram urban—the rate was no less than 265 per 1000 births—a rate for which the district medical officer is apparently unable to account. Mr. Vacher, in dealing with the subject of stillborn children, points out that stillbirths are not officially recognised, and that it is open to any one to bring the body to the sexton, together with a certificate from the midwife or nurse, and to have the body thereupon interred. It is desirable, Mr. Vacher insists, that every birth, stillborn or otherwise, should be subject to compulsory registration. The zymotic death-rate in Cheshire during 1896 amounted to 1·6 per 1000, the rate for diphtheria and croup being 0·35 per 1000, and that for fever 0 15. It appears that there is very little provision made in the county for the bacteriological examination of suspicious cases, and many of the medical officers of health lament this fact in their reports. An instructive outbreak of enteric fever occurred at the County Asylum, Upton, and was traced to the agency of specifically polluted water infected through the admission of surface water past a ball valve, which had dropped down during a diminution of pressure in the mains. With regard to the progress of notification, it is interesting to read that at the beginning of 1897 there were but two districts, Congleton municipal borough and Nantwich rural district, which had not adopted the Act. Some progress has been made in isolation accommodation, but, as Mr. Vacher observes, such accommodation is still singularly inadequate to a population of 572,000. The County Council appear to have been most energetic in pressing the provisions of the Isolation Hospitals Act, 1893, but it has not been an easy matter to persuade the authorities to undertake the necessary expenditure. In some cases the local authorities seem to have preferred to proceed under the provisions of the Public Health Act, 1875, and in such cases the County Council were willing to subscribe towards the cost of erection and maintenance provided they had seats on the Joint Hospital Board. It was held, however, by the Local Government Board, to whom the question was submitted, that a county council could only contribute to such hospitals as were erected under the Isolation Hospitals Act.

Hackney Sanitary District.—Dr. King Warry reports that, in his opinion, the inability on the part of the Metropolitan Asylums Board to remove in the summer of 1896 all cases of scarlet fever concerning which application for admission was made resulted in a spread of the disease, and he insists in this connexion on the desirability of removing first cases. Dr. Warry furnishes the subjoined table showing the number of applications for removal to hospital which were made in certain cases:—

Number of applications	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
Cases removed after above number of applications... ...	97	93	28	14	9	9	9	1	3	3	2	–	1	3	1

In the matter of diphtheria Dr. Warry furnishes very strong evidence for believing that one of the Board schools acted during 1896 as a centre for the propagation of diphtheria; and it is pointed out that, although it is not possible to connect each case with a preceding one, this fact does not destroy the thesis that the probable infection at school was the cause of the exceptional incidence on the children attending that school. The existence of mild unrecognised cases has, he rightly observes, been definitely established. As a means of diminishing the power of schools for harm in the propagation of diphtheria Dr. Warry advises that during the prevalence of the disease in a neighbourhood the schools shall frequently be examined by a medical man, and that any cases of sore throat shall at once be excluded from the school, a notification as to the exclusion being sent at once to the medical officer of health of the district. Analyses from the water of the River Lea show that its pollution continues, and Dr. Warry has no hesitation in stating that it is distinctly dangerous to the health of those who are exposed to its effluvia. The London County Council constructed a pool alongside the river, which is replenished by water percolating through from the river, and proposed, it seems, to encourage bathing by the erection of sheds for undressing, &c. Water was only to be admitted into the pool by percolation, or, if necessary, at times of high water or during the floods. Dr. Warry, however, strongly opposed the proposal, as he considers it highly dangerous for bathing to take place in such water as had been admitted at high tide or during periods of flood. Organisms of disease are, Dr. Warry thinks, plentiful in the Lea water, and he considers it "extraordinary that anyone should entertain the idea that water of less purity than that used for domestic purposes is good enough for bathing in." The project has since been abandoned. Dr. Warry reports that there is reasonable ground for suspicion that during the summer of 1896 certain cases of enteric fever were caused by the consumption of oysters.

Huddersfield Urban District.—Mr. E. G. Annis is to be congratulated upon his first annual report, and he has laid a capital foundation for the future study of the statistics of the district by constructing a Huddersfield Life Table. This table has not been altogether agreeable in its revelations to the people of Huddersfield, and it goes to show that there is much to be done in the district before the sanitary authority can congratulate themselves upon the expectation of life of the inhabitants. It seems that at birth the expectation is 12·79 years less than that of England and Wales as a whole, 10·13 years less than that of London, 3·72 years less than Glasgow, and 13·66 years less than Brighton; while, on the other hand, the expectation of Huddersfield is 1 90 years greater than that of Manchester township; there does not

Digitized by Google

seem to be much difference in the relative rates at the different age periods. The recorded death-rate of Huddersfield was 16·5 per 1000, a rate which places it in this particular below only four of the thirty-three great towns for the same period, but when regard is had to the corrected death-rate it is found that Huddersfield is as low down as fourteenth in the list of corrected death-rates.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6828 births and 5180 deaths were registered during the week ending August 28th. The annual rate of mortality in these towns, which had been 29·5 and 28·7 per 1000 in the two preceding weeks, further declined last week to 24·6. In London the rate was 20·4 per 1000, while it averaged 27·4 in the thirty-two provincial towns. The lowest death-rates in these towns were 14·4 in Huddersfield, 15·5 in Bristol, 17·2 in Swansea, and 18·5 in Bolton; the highest rates were 32·5 in Salford, 34·5 in Birmingham, 41·9 in Hull, and 47·6 in Preston. The 5180 deaths included 1783 which were referred to the principal zymotic diseases, against 2368 and 2319 in the two preceding weeks; of these, 1490 resulted from diarrhœa, 106 from measles, 71 from whooping cough, 45 from "fever" (principally enteric), 39 from diphtheria, and 32 from scarlet fever. The lowest death-rates from these diseases were recorded in Huddersfield, Swansea, Bristol, and Birkenhead; and the highest rates in Birmingham, Salford, Hull, and Preston. The greatest mortality from measles occurred in Birmingham, Oldham, Manchester, Blackburn, and Preston; from whooping-cough in Sunderland; from "fever" in Derby; and from diarrhœa in Wolverhampton, Birmingham, Leicester, Salford, Preston, and Hull. The mortality from scarlet fever showed no marked excess in any of the large towns. The 39 deaths from diphtheria included 28 in London. No fatal case of small-pox was registered last week in any of the thirty-three large towns; and no cases of this disease were under treatment during the week in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3448, against 3239, 3341, and 3400 on the three preceding Saturdays; 356 new cases were admitted during the week, against 376, 347, and 340 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 118 and 119 in the two preceding weeks, declined again last week to 102, and were 64 below the corrected average. The causes of 48, or 0·9 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Nottingham, Leeds, Hull, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Norwich, Leicester, Birkenhead, and Burnley.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·0 and 21·6 per 1000 in the two preceding weeks, declined again to 19·6 during the week ending August 28th, and was 5·0 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 17·3 in Leith and 17·4 in Edinburgh to 23·7 in Greenock and 23·8 in Paisley. The 585 deaths in these towns included 96 which were referred to diarrhœa, 23 to whooping-cough, 8 to "fever," 7 to scarlet fever, 2 to measles, and 1 to diphtheria; in all, 137 deaths resulted from these principal zymotic diseases, against 156 and 187 in the two preceding weeks. These 137 deaths were equal to an annual rate of 4·8 per 1000, which was 3·9 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 113 and 147 in the two preceding weeks, declined to 96 last week, of which 50 occurred in Glasgow, 12 in Edinburgh, and 10 in Paisley. The 23 deaths from whooping-cough showed a slight further increase upon the numbers recorded in recent weeks, and included 12 in Glasgow, 5 in Dundee, and 3 in Greenock. The *deaths* referred to different forms of "fever," which had been 4 in each of the two preceding weeks, rose to 8 last week, of which five occurred in Glasgow. The fatal cases of scarlet fever, which had been 12 and 5 in the two preceding weeks, rose again to 7 last week, and included 4 in Edinburgh and 2 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 58 and 62 in the two preceding weeks, further rose to 77 last week, and exceeded by 10 the number in the corresponding period of last year. The causes of 29, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·5 and 24·3 per 1000 in the two preceding weeks, further declined to 23·0 during the week ending August 28th. During the past eight weeks of the current quarter the rate of mortality in the city has averaged 23·5 per 1000, the rate during the same period being 21·4 in London and 18·4 in Edinburgh. The 154 deaths registered in Dublin during the week under notice showed a decline of 9 from the number in the preceding week, and included 39 which were referred to the principal zymotic diseases, against 51 and 39 in the two preceding weeks; of these 32 resulted from diarrhœa, 3 from "fever," 2 from scarlet fever, 2 from diphtheria, and not one either from small-pox, measles, or whooping-cough. These 39 deaths were equal to an annual rate of 5·8 per 1000, the zymotic death-rate during the same period being 5·4 in London and 3·0 in Edinburgh. The fatal cases of diarrhœa, which had been 39 and 31 in the two preceding weeks, were 32 last week. The deaths referred to different forms of "fever," which had been 4 and 2 in the two preceding weeks, rose again to 3 last week. The 2 fatal cases of scarlet fever were within one of the number recorded in the preceding week; and the 2 deaths from diphtheria exceeded the number registered in any recent week. The 154 deaths in Dublin last week included 41 of infants under one year of age and 27 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from those recorded in the preceding week. Seven inquest cases and 3 deaths from violence were registered; and 47, or nearly a third, of the deaths occurred in public institutions. The causes of 5, or more than 3 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN CROSS, 1st Life Guards, is selected for promotion into the Royal Horse Guards, vice Surgeon-Major Mitchell (retired). Surgeon-Lieutenant Waring assumes temporary Medical Charge of Women and Children, Aldershot. Brigade-Surgeon-Lieutenant-Colonel Macnamara departs for service in Malta and Surgeon-Major G. F. A. Smythe for service in Egypt. Surgeon-Captain Bray joins at Colchester for duty. Surgeon-Captain Hennessy is warned to be in readiness for service in India.

Brigade-Surgeon-Lieutenant-Colonel M. M. Gallwey is placed on retired pay. Surgeon-Lieutenant-Colonel Swayne to be Brigade-Surgeon-Lieutenant-Colonel, vice Gallwey.

INDIA AND THE INDIAN MEDICAL SERVICE.

The Queen has approved of the following admissions to Her Majesty's Indian Medical Service:—To be Surgeon-Lieutenants:—John George Patrick Murray, Samuel Anderson, Francis Hope Grant Hutchinson, James Leslie Majoribanks, Alexander Fenton, James Allen Dredge, and Robert Welland Knox. The Queen has approved of the retirement from the Service of the under-mentioned Officers:—*Bengal Establishment:* Brigade-Surgeon-Lieutenant-Colonel Charles John Walford Meadows, Surgeon-Lieutenant-Colonel Alfred Henry Williams, and Surgeon-Lieutenant-Colonel Augustus Edward Richard Stephens. *Madras Establishment:* Brigade-Surgeon-Lieutenant-Colonel Henry James Hazlett and Surgeon-Lieutenant-Colonel Stanley Locker Doble. *Bombay Establishment:* Brigade-Surgeon-Lieutenant-Colonel George Archibald Maconachie and Surgeon-Lieutenant-Colonel Saunders Barton Haliday.

Digitized by Google

NAVAL MEDICAL SERVICE.

The under-mentioned Surgeons have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet:—William Edward Home, Richard Aubrey Fitch, Henry Bullen Beatty, William Spry, Percy Edmund Maitland, James Joseph Walsh, John Moore, Cyril James Mansfield, Robert Hickson, Herbert Parke Shuttleworth, John Lowney, and Octavius Stephens Fisher.

VOLUNTEER CORPS.

Royal Engineers: 1st Cheshire: William Lawton to be Surgeon-Lieutenant. 1st Lanarkshire: Surgeon-Major A. Meehan resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the corps on his retirement. *Rifle:* 1st Volunteer Battalion the King's Own (Royal Lancaster Regiment): Surgeon-Captain J. Murray to be Surgeon-Major, to resign his commission; also to be permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement. 3rd Volunteer Battalion the South Staffordshire Regiment: Surgeon-Lieutenant E. Morton from the 2nd Volunteer Battalion the Worcestershire Regiment, to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Oxfordshire Light Infantry: Surgeon-Captain J. J. A. Raye resigns his commission.

VOLUNTEER INFANTRY BRIGADE.

Tyne and Tees Brigade: Surgeon-Lieutenant-Colonel A. Wilson, 2nd Volunteer Battalion the Northumberland Fusiliers, to be Brigade-Surgeon-Lieutenant-Colonel on being appointed Senior Medical Officer to the Brigade.

THE HEALTH OF THE ARMY IN INDIA.

We have frequently called attention to the fact that it is quite a mistake to suppose, and a libel on the Indian Government and the military authorities to assert, that nothing has been, or is being, done to improve the moral and social condition of the British soldier in India or to strengthen his powers of self-restraint and increase his self-respect. It is on account of the large and increasing prevalence of venereal disease in India, in spite of all that has been attempted in these directions, that most sensible people are agreed as to the necessity of having recourse to restrictive measures of a physical kind. Our army in India is a celibate army, composed of men of an age when the animal passions are strongest and the judgment weakest, and no one who regards human nature as it is and looks the facts fairly in the face can doubt that under such circumstances there must be a great deal of yielding to temptation where so dominating an instinct as the sexual instinct is concerned. But we altogether deny that those who hold that venereal disease should, in the interest of public health, be treated like any other contagious disease are neglectful of the application of moral measures and influences. By all means let those who believe in the adequacy of these measures to accomplish the end in view try them. It is somewhat pharasaical, however, for those who are happily married to inveigh against the sin of incontinence in the case of soldiers living in enforced celibacy. An article appeared in the *Times* of Aug. 24th last on the British soldier and habits of self restraint, in which all that has been done of late years for the soldier serving in India is set forth, especially in the directions recently reported upon by the Army Temperance Association and the Army Health Association. It is remarkable how much has been accomplished during the last quarter of a century.

Surgeon-Major Horace Henderson Pinching, who took part in the late Mission to Abyssinia, has been granted Her Majesty's authority to wear the Insignia of the Order of the Star of Ethiopia of the Second Class conferred upon him by the Emperor Menelik II.

STEAM MOTOR DUST WAGGONS.—The Urban District Council of Chiswick has just commenced the collection of dust and house refuse by motors, the first of two "steam tip waggons" ordered for the purpose having commenced to work last week. Mr. Ramsden, the surveyor to the district council, reports that a week's experience with one of the cars shows that they are very easily controlled and far more economical than horse labour. The steam waggon does the work of three ordinary carts, and Mr. Ramsden estimates that the council will save between £500 and £600 a year by the adoption of the new system.

"Audi alteram partem."

BATTEY'S OPERATION.

To the Editors of THE LANCET.

SIRS,—Is Battey's operation a justifiable procedure to prevent the recurrence of pregnancy in the case of those who have been the subjects of severe dystocia from whatever cause arising; and if so, under what circumstances may the operation be permissible? This question has probably occupied the thoughts of many medical men at one time or another, but I have not seen any literature bearing on the subject, and I should be glad to hear of any such.

The patient whose case suggested this inquiry to me is thirty-four years of age, and was delivered of a male child on the morning of June 10th last. Her previous (and first) confinement took place eight years before, when she was in labour for more than three days. On that occasion there was continuous, and at times profuse, hæmorrhage for eight hours previous to the commencement of labour and it did not cease until the birth of the child; it was evidently due to separation of part of the placenta as the secundines were born with the child, a portion, however, remaining behind which did not come away until the fifth day. Delivery was effected by forceps and the perineum was badly torn. Stitches were inserted into the perineum on three occasions during the puerperium; in the first place immediately after the confinement, secondly on the fifth day, when the passage of the remainder of the placenta had torn open the wound, and thirdly on the seventh day, when the bowels acted and scybalous masses of fæces were passed through the vagina, the back stitches again giving way. Union did not take place, and for eleven months the patient had no control over the bowels, which were evacuated through the vagina, and she was in a pitiable state. At this time perineal repair was performed at the Chelsea Hospital for Women. It was remarked that the case was the worst rectal tear which had been operated on at the hospital. The result of the operation was distinctly good, inasmuch as only a small fistulous opening remained in the bowel through which the motions, when loose, occasionally passed to a slight extent into the vagina. She was told on her discharge, that the perineum would probably not bear the strain of another confinement.

At the next confinement, which happened last June, as already mentioned, she delayed sending for me, so that the child was actually born on my arrival, the first and second stages having been remarkably rapid. The perineal tear on this occasion, although extensive, did not actually involve the sphincter ani. Otherwise the labour was easy and normal. I stitched up the perineum and conducted the case in the usual way. Union has not, however, been complete. The present condition, four weeks after confinement, is, however, on the whole, very satisfactory. In front of the anus, which, as already mentioned, has not been involved, is a small sinus communicating with the vagina, being separated from the vaginal orifice by a fairly strong bridge of cicatricial tissue. The patient can get about with moderate comfort and expresses herself as feeling very different as compared with the state she was in after her previous confinement. The operation required on this occasion to repair the perineum will be a comparatively easy one. The patient assures me she cannot undergo the ordeal of another confinement which might reasonably be expected to occur under existing circumstances, and with the object of preventing this she has asked my opinion as to the advisability of undergoing an operation for removal of the ovaries.

This operation has a moral as well as a scientific aspect. It is a recognised procedure in various diseases of the uterus and adnexa as well as in certain neuroses such as hystero-epilepsy; but in a healthy woman in the prime of life is it justifiable to remove the ovaries because her confinements have been complicated by accidental hæmorrhage and severe perineal tear, even although there is a prospect of her future confinement or confinements being similarly complicated? I think that most medical men would be inclined to decide against the operation under circumstances such as this, and

Digitized by Google

this for the following reasons: (1) the second confinement was in every way more satisfactory than the first, as there was no excessive hæmorrhage and, apart from the perineal tear, which was much less extensive than on the previous occasion, the labour was easy and normal; (2) there is every probability that should the patient again become pregnant, her confinement will be easier than heretofore; (3) it may be possible to prevent any laceration of the perineum by inducing premature labour at a suitable time, when the child will be smaller than at term; and (4) perineal rupture is seldom a complication of labour which is fraught with actual danger to life. Apart from these considerations, the responsibilities and claims of married life cannot be overlooked; and however willing a husband may be to abstain from sexual intercourse with his wife, it is not right that such restrictions should be imposed upon him unless there be a very good cause for so doing. Another question which must arise is, can a married couple in the prime of life live together as happily after such an operation as before?

Finally, what are the guiding principles to be followed in deciding for or against the prevention of pregnancy by means of Battey's operation, providing always that the patient desires the operation and her husband, understanding the risk of the operation and its consequences, gives his consent in writing? In the event of removal of the ovaries being determined upon, ought the operation to be performed by the vaginal method or by abdominal section? The latter is usually chosen as being the more satisfactory and complete. It has been proved beyond doubt that the removal of diseased ovaries does not unsex a woman. Can the same be said for the removal of ovaries presumably healthy?

I am, Sirs, yours faithfully,

JAMES KENNETH WATSON, M.D., C.M. Edin.

Byfleet, Surrey, Aug. 21st, 1897.

"FIRST-AID TO SAILORS."

To the Editors of THE LANCET.

SIRS,—With the annotation on "First-aid to Sailors," which appeared in THE LANCET of Aug. 28th, those most deeply interested in spreading knowledge of the subject have every reason to be satisfied, excepting in respect of some comments towards the end, and these are evidently due to lack of full information. At the Ambulance Classes held under the auspices of this society the lecturers, being reminded of the circumstances that accidents to sailors do occur in places where it may be impossible to obtain qualified surgical assistance for weeks or months, extended their teaching of how to handle dislocations, fractures, hæmorrhage, burns, &c., beyond the limits of "First-aid to the injured," into what they are pleased to call "Second-aid," giving practical demonstrations. Mr. C. Alan Palmer, to whom this society is much indebted for assistance during a long period, knew of this practice when writing as he did. Having seen and heard much of permanent deformity and intense suffering due to the absence of First-aid knowledge among sailors, being greatly interested in the question, and jealous of Mr. Palmer's credit, I hope to be excused for troubling you with this letter and that you will give insertion to it, or its cardinal points, in your next issue.

I am, Sirs, your obedient servant,

Aug. 21st, 1897. A. G. FROUD, Lieutenant R.N.R.

THE MALARIAL HAND.

To the Editors of THE LANCET.

SIRS,—It is well known that long residence in a malarial climate causes, in a large majority of cases, such changes in the colouring matter of the skin that, instead of "sunburn" a peculiar "putty-like" appearance is produced. With some this appearance disappears after a short residence at home, with others it is permanent. This "West-coast complexion" is so commonly recognised as to need no comment here. The peculiar phenomenon to which I wish to draw the attention of the profession is one which I have called "the malarial hand." I have noticed during my sojourn in the Niger Territories, among those Europeans who have resided on the Niger more than two years, a singular rose-pink colouration of the skin over the thenar and hypothenar eminences and also over the under surfaces of the last phalanges of both hands. This colouration comes on imperceptibly and increases gradually until the appearance is as if these surfaces had been dipped in red ink. I have not noticed it in persons of any particular complexion, but it seems to affect fair and dark alike, and it always appears simultaneously on both hands, never on one alone or on one before the other. It would be very interesting to hear if a similar manifestation exists in other malarial climates, and if so to what it has been ascribed. Personally I am not yet in a position to give an opinion on the subject, but would be very interested to hear that of *confrères* who have noticed the peculiarity.

I am, Sirs, your obedient servant,

EDWARD E. CRASTER,

Principal Medical Officer, Niger Territories, West Africa.

Aug. 10th, 1897.

DR. HOLME WIGGIN ON INFANTILE INTUSSUSCEPTION: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—Permit me to correct a trifling inaccuracy in Dr. Holme Wiggin's interesting paper on Infantile Intussusception in THE LANCET of Aug. 28th. "Case 18" and "Case 19" refer to the same case and not to two separate cases. The mistake has evidently arisen from two abstracts having been made of the same case, one from a reference to my own name and another from a reference to that of Mr. Winter. The case was reported and figured by myself by permission of Mr. Winter, the honorary surgeon, under whose care the case was admitted to the Wolverhampton General Hospital.—I am, Sirs, yours faithfully,

EDWARD DRANESLY, M.D. Lond., F.R.C.S. Eng.,

Hon. Casualty Surgeon, Wolverhampton and Staffordshire General Hospital.

Waterloo-road, S., Wolverhampton.

IS "MEDICAL DEFENCE" DEROGATORY TO THE DIGNITY OF MEDICAL MEN?

To the Editors of THE LANCET.

SIRS,—To the competent observer of medical affairs this must necessarily appear to be the vital question of the day in the medical world, on the answer to which will turn the future and the destinies of the medical profession. For those who should take the lead in defence of medical rights and interests rely, in refusing to do so, almost solely on the assertion, or assumption, or insinuation that for them or for the bodies they represent to do so would involve some loss of dignity and prestige, some humiliation, some course of conduct or some motive less worthy than that pursuit of science which should, they contend, be the sole aspiration and motive of its devotees. The coarsest form assumed by this assertion is that medical defence is trades unionism. The more refined terms in which it is expressed are a deprecation of it in the particular case or cases—an assumption that it would be an unsatisfactory new departure for bodies that have been and should be devoted to science; sometimes an evasion, sometimes a more direct repudiation of such functions—with or without an audible deprecation of them; but whatever terms are used or course adopted, the reason, expressed or implied, is that regard for our common rights and material interests is beneath alike the magnanimous practitioner of a humane profession and the earnest student of science.

To quote the expressions of individuals would unduly restrict proper criticism. Classical illustrations may, however, be given. Such is the recent evasion by the Council of the Royal College of Surgeons of England of the applications made to it to employ its disciplinary powers in restricting the exploitation of its Members for the profit of the lay public in methods and under conditions opposed to the ethics of the profession. In this instance the application was evaded by an oracular reply: "Such an exercise of its powers would interfere with the legal rights of its Members." But this was the question to be considered, and it is not considered by the answer being assumed. The legal right to practise does not include or legalise conduct which the College on proper proceedings pronounces to be "disgraceful in a professional respect." The College would not hesitate to denounce direct touting and advertising or covering to be "disgraceful conduct in a professional respect." If there is no distinction between this and the indirect touting, advertising, and profit earning

Digitized by Google

for lay persons complained of, then these also are "disgraceful conduct in a professional respect." If there be a distinction it is not unreasonable to expect the College to define it in the interests both of the profession and the public, and not merely to postpone the evil day with complete indifference to the ill effect of existing conditions on "the study and practice of the art and science of surgery," which it is the function of the College and duty of the Council to "promote."

At the recent half-yearly meeting of the Fellows of the College this was the keynote of the occasion. "Admitting, for the sake of argument, that By-law 15 were binding on the Council, would it not be most deplorable for this great scientific institution to become identified with individual interests, however meritorious, and mixed up with actions at law?" That the most essential rights and privileges of its Members in "the study and practice of the art and science of surgery" might be involved in such actions was admitted, but was not regarded as rendering participation by the College in such actions for the defence of those rights less "deplorable"; and in this instance also the opposition offered depends entirely on the assumption that the defence of their rights and interests is derogatory to the dignity and unworthy the attention of men engaged in the pursuit of science and of an institution devoted to the advancement of science.

Even the Hunterian Oration has become the vehicle of the same views enunciated on the same assumption of axiomatic certainty. In other more or less widely distinct scenes and centres contempt for, and dislike of, what is called "medical defence" finds no less confident and influential expression. No one who has attentively watched the proceedings of the General Medical Council can have failed to perceive the dislike manifested to this subject, or the lofty air of superiority with which it is, whenever possible, relegated to a later day. At the last meeting, after a year's successful evasion by the exclusion and suppression of letters, the Council was brought to the consideration of its duties in maintaining inviolate the rights of registered practitioners under the Medical Acts. Any real and open debate of a subject so shocking to all sense of propriety was avoided by means of a motion of doubtful regularity that decided the point at issue without considering it, not ascertaining or even permitting expression of the views of members upon the merits, but accepting as sufficient the *ipse dixit* of an irresponsible legal adviser. But it is encouraging that on this occasion the closure met with resistance. In the late extraordinary general meeting of the Metropolitan Counties Branch of the British Medical Association it may almost be said that the whole strength of the opposition to medical defence consisted either of the argument that the association is a scientific body, and that medical defence is unworthy of a great scientific institution, or of fears of difficulties and of dangers of becoming involved in discreditable cases—of dissatisfaction, dissension, and disunion—put forward with really remarkable effect upon the result of the meeting. A final instance may be given of no less importance than these, and perhaps even more convincing. The exclusion of the Members of the College from all share in the government of their great corporation is defended on the ground that the presence of Members of the College, or even of Fellows representing them, on the Council would mean the importation into the transactions of the Council of discussion and even of action relating to the rights and interests and affairs of the Members throughout the world; whilst a part of the same argument is that the College is a scientific body—a silent repudiation of its functions as our greatest professional guild. Therefore, before the opposition to medical defence on the part of the leaders of the medical profession can be overcome it is necessary to convince them that medical defence, properly understood, is not derogatory to the dignity of medical men; and that in the eyes of their professional brethren the assumption or assertion that it is derogatory is not merely a grave error, but a grave offence.

I am, Sirs, your obedient servant,
REGISTERED PRACTITIONER.

"GLYCERINATED CALF VACCINE LYMPH."

To the Editors of THE LANCET.

SIRS,—In the first leading article in THE LANCET of Aug. 28th it is said: "For the last six or seven years Dr. Monckton Copeman has paid special attention to the subject of glycerination of calf vaccine lymph; indeed, it may be gathered that he was one of the first, if not the first, to put this method into actual practice." When I was a student at the London Hospital between the years 1868 and 1872 there was a small-pox scare in London, and the staff thought it desirable that hospital patients who did not object should be vaccinated or re-vaccinated, and as the supply of lymph was short the "happy thought" of diluting the vaccine with glycerine was adopted, and, I believe, with great success.

I am, Sirs, yours truly,
AN OLD LONDON HOSPITAL HOUSE SURGEON.

Aug. 30th, 1897.

"HOSPITAL ABUSE."

To the Editors of THE LANCET.

SIRS,—I can congratulate you heartily on the two articles in which your Special Commissioner so ably and so truthfully sums up the situation in Birmingham. Some ten years ago I was resident officer in the General Hospital and in the Queen's Hospital and at the General Dispensary. My remembrance of the abuse of these charities (?) confirms your correspondent in every way. The worst abuse I found existed at the General Dispensary, especially after the committee weakly yielded to the clamour of the organised workmen and expunged the words "object of charity" from their tickets. Soon after my appointment to the General Dispensary I became aware of two glaring cases of abuse, which I confirmed by personal inquiry and reported to the committee, giving details of each case. My zeal was soon quenched by a letter informing me that such reports should proceed, if from anybody, from the secretary, and that *my* work was to attend to the people who brought tickets.

I am, Sirs, yours faithfully,
Aug. 30th, 1897. A GENERAL PRACTITIONER.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

XII.—BIRMINGHAM *(continued)*.[1]

The Eye Hospital.—The Ticket and Registration System.—The Lock Hospital and Commercialism.

AT the Eye Hospital various proposals have been made with a view to limiting the number of patients. It was suggested that only sixty, or at most a hundred, new patients should be seen in a day. But who would select these patients? If it were only the first-comers who were admitted this might mean the neglect of very urgent cases because they happened to come last. Also, it would be very hard to send back without advice those who had travelled perhaps forty or fifty miles to reach the Eye Hospital. What would be better is a method of registration and the appointment of inspectors to make inquiries at the patients' homes and verify the truth of the details given for registration. One of the visiting staff of the Eye Hospital told me that nearly every week one or more of his private patients would declare that it was foolish to pay fees when their friends went to the hospital and obtained the same advice for nothing. A patient from a neighbouring town who made about £10 a week was reproached for going to the Eye Hospital and he replied: "I know I can afford to pay, but I am not going to pay. Is it because I have been steady all my life and have saved money that I am to be punished for these virtues by being called upon to pay? If I had

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *concluded*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *concluded*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; (5 *concluded*) Jan. 23rd, 1897, Manchester; (6) Feb. 6th, 1897, Leeds; (6 *concluded*) Feb. 13th, 1897, Leeds; (7) April 17th, 1897, Coventry; (8) May 1st, 1897, The Royal London Ophthalmic Hospital; (9) May 8th, 1897, France, United Action and Legislative Action; (10) May 15th, 1897, Leicester; (11) June 5th, 1897, Nottingham; (12) July 31st, 1897, Birmingham; and (12 *continued*) Aug. 14th, 1897, Birmingham.

Digitized by Google

been thriftless and a drunkard I should have been a proper patient and admitted without question." Some little while ago my informant removed a cataract from a person of limited means and was paid a 12-guinea fee for the operation. This patient had a friend who also suffered from cataract. The friend had a pension of £150 a year and some £3000 to £4000 capitalised. This man went to the Eye Hospital, paid a shilling registration fee, and had his cataract removed. Afterwards he used to laugh at his friend, exclaiming, "How much did your eye cost you? Twelve guineas; mine only cost twelve pence."

Undoubtedly at the Eye Hospital tickets are given away too freely. People go there who have only a stye in the eye or a slight cold. These trivial cases, at least, might go to the general practitioners. But when the New Eye Hospital was built—and as a structure it is one of the best eye hospitals in England—the sale of tickets had to be forced up from £1500 to some £3000 a year. Many subscribers in the course of the year ask and pay for more tickets. This they often do very reluctantly; but there is such a demand for these tickets that subscribers are compelled to purchase many more tickets than they originally intended. There are business connexions, workmen and others, whom a subscriber is so often called upon to oblige, and whom he cannot very well refuse. It must be borne in mind that a man in business who is solicited for a ticket by a customer cannot very well ask his customer whether the person for whom the ticket is intended is a fit object of charity. A business man's first thought is to oblige his customer. By the side of this necessity the question of hospital abuse holds a very small place in his mind. All these circumstances enabled the managers of the Eye Hospital to save in four or five years enough to build a new wing that cost some £5000, and this without asking the public for a single penny. Any patient going to this hospital is seen for the first time, even if he has not a ticket, and if the case is urgent he will be seen again so long as the urgency continues; afterwards he must obtain a ticket if he wishes for further advice and medicine. This system works very well from the financial point of view. The subscriptions in 1883, before the new hospital was built and before any effort was made to force them up, amounted to £1361. When the ticket system was enforced the subscriptions rose in 1889 to £2409, in 1893 to £2800, and in 1894 to £3080. Though the ticket system favours much abuse, it is difficult to suggest its abolition in the face of these financial results.

In the eye department of the Queen's Hospital it was decided not to see more than twenty-five new cases in each of the two days devoted to diseases of the eye. This made fifty new cases per week, and as many as 150 new patients have applied in the course of a week. The last comers were not admitted, and it often happened that from twenty to thirty patients went away unrelieved. It also frequently occurs that ophthalmic surgeons receive in their private practice patients who have grown tired of waiting for their turn at the hospitals, and these patients from the hospitals have not only paid the guinea consultation fees, but they have also sometimes paid operation fees, and this at the ordinary rates. This fact in itself indicates the high-class character of many of the patients at the eye hospital. It also opens out the question as to whether what would constitute an abuse at a general hospital is to be considered an abuse at a special hospital. For a general hospital it may be urged that anyone who can pay a 2*s.* 6*d.* fee or who can subscribe to a provident dispensary has no right to go to the hospital. But the ophthalmic surgeon's fee is generally a guinea, and therefore it is urged in some quarters that all those patients who cannot pay guinea fees are entitled to go to the Eye Hospital; this it is that explains why a much better class of patients frequent such hospitals. At Birmingham there is also a much better class of patients at the Ear and Throat Hospital. Many of the patients have been in the habit of paying 5*s.* fees to their ordinary medical man, but cannot afford to give a guinea to the consultants who make this class of disease their speciality. Therefore, if, as sometimes occurs, the general practitioner fails to effect a cure such patients resort to the Ear and Throat Hospital. Here they gain admission either by ticket (and six tickets can be obtained for a guinea) or else by paying a registration fee of 3*s.* 6*d.* In-patients are only admitted by ticket unless it be an urgent case, and very poor patients are accepted free of any charge when especially recommended.

The payment of registration fees is not looked upon with favour by the majority of medical men. The sum charged is too large to cover the cost and trouble of registering the applicant's name, &c., and it is not sufficient to defray the cost of his treatment. Nevertheless, in its February, 1895, issue, *Forward*, the organ of the Hospital Saturday Fund, says in its leading article: "The registration fees are regarded by most of the patients at what are termed the free hospitals as payments for value received. The Queen's Hospital makes a charge of a shilling per patient; at the Women's Hospital the charge is half-a-crown, with a repetition of the payment every month if the patient continues in attendance. Similar charges are made at the Children's Hospital, the Skin and Lock Hospital, the Ear and Throat Infirmary, the Dental Hospitals, and others. The registration fees represent in the aggregate upwards of £4000 per annum. At the Queen's Hospital they amount to 39 per cent. of the total subscription list, at the Children's Hospital 36·5 per cent., at the Skin and Lock Hospital 209 per cent., at the Women's Hospital 200 per cent., at the Ear and Throat Hospital 81 per cent., and at the Dental Hospital 238 per cent." Thus it will be seen that the patients, in the main, think they are paying fully for all they receive; and, on the other hand, that in some of the hospitals they do by their registration fees cover more than two-thirds of their cost, since for £100 subscribed more than £200 are received in registration fees. This system dates back to the year 1870, when the experiment of a free hospital was made at the Children's Hospital. As there was no restriction to the admission of patients the number of applicants soon became so great as to be absolutely unmanageable. It was then decided to charge a sixpenny registration fee, and this kept away the very trivial cases. In 1875 the Queen's Hospital followed this example by instituting a shilling registration fee, and other hospitals soon did the same.

Perhaps the strongest complaints in regard to registration fees are against the Skin and Lock Hospital. Not only does this hospital advertise and charge a very high registration fee, but there are baths for which a charge is also made. Finally, and to ensure a plentiful supply of patients who are practically paying patients, the consulting hours are in the evening. Thus a workman who has contracted a venereal disease can, without inconvenience to himself, be treated after his working hours. It is a good thing, not only for the patient, but more particularly for the public at large, that all those who suffer from a contagious disease should have every opportunity of getting cured so that they should not spread the complaint to other and more innocent persons. Still, it does seem peculiar that there should be greater facilities for the cure of shameful diseases than for ordinary complaints. If the visiting staff of a hospital for venereal disease may be consulted at the hospital in the evening and after the day's work, why should not the visiting staff of all the hospitals be at the disposal of the public after other than the wage-earning hours of the day? It seems odd that those who suffer from venereal disease should be especially privileged, and under such circumstances it is not surprising that the Lock Hospital should be denounced as an institution run on a commercial basis. This permeation of commercialism in hospital management is in part the fault of the medical men themselves, for they do not attend with sufficient assiduity the meetings of the management committee, and then the lay members of these committees, who are for the most part commercial men, naturally introduce non-professional ideas and policy. The decision of the committee of the Lock Hospital that the honorary surgeons should receive patients at the hospital in the evening certainly shows a tendency to truckle to the working-class population — a tendency which, however, is not based on any abstract principle, but is due rather to the fact that of late the working class has become one of the chief paymasters. This, indeed, is what I have been made to feel throughout the whole inquiry, and every question asked seems to have been echoed by the other question: "Yes; but there is the Hospital Saturday Fund, and what will the workmen say?" Three out of every four workmen in Birmingham subscribe to the Hospital Saturday Fund, and they raise so large a sum that they hold the medical charities of Birmingham in their grip. There is hardly a hospital in the town which would not be bankrupt to-morrow if the workmen withdrew their support. This is a state of affairs pregnant with so many threatening contingencies that it must be studied carefully.

(To be continued.)

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Munificent Gifts to Newcastle Charities.

MR. HILTON PHILIPSON, a well-known solicitor and coal owner, son of the late Mr. Ralph Park Philipson, who was for many years the town clerk of Newcastle, has given the sum of £2000 to the Home for Destitute Crippled Children. This most valuable institution, for which the town is mainly indebted to Mr. W. T. Sanderson, is destined to do an immense amount of good in the neighbourhood. A new home at Gosforth is just ready for occupation, but it still has a debt of £1500 upon it.—Mr. John Hall, a wealthy ship-owner in Newcastle, has offered to build and equip at his own expense a new infirmary, provided that the building be erected upon another site and that the sum of £100,000, already raised by the ex-Mayor of Newcastle, Mr. Riley Lord, for the purpose of building a new infirmary on the present site, be transferred to the sustentation fund. Hitherto the infirmary authorities have utterly failed in getting from the town council another site or even an augmentation of the present one. The town council is the only source from which an eligible site can be obtained, and it is to be hoped that this generous offer of one of Newcastle's most prominent philanthropists will induce the council to reconsider its refusal to grant a site. Mr. John Hall's name will go down to posterity as one of Newcastle's greatest benefactors should it be found possible to profit by his noble offer.

The Policeman's Baton.

An inquest has just been held upon the body of a pitman, who died in the Royal Infirmary, Newcastle-upon-Tyne, from fracture of the skull the result of a blow from a policeman's baton. A verdict of manslaughter has been returned, and in due time it will have to be explained how the deceased's head got in the way of the baton. In the meantime the case is another illustration of the danger of striking a man on the head with such a weapon as the policeman's truncheon.

Home for Aged Miners.

On Saturday last, at Barmoor, a few miles from Newcastle-upon-Tyne, the foundation-stone of a home for aged miners was laid by Mrs. J. B. Simpson upon ground given by the Stella Coal Company. The home is to consist of eight one-storey and two two-storey cottages, and it will be erected at the sole expense of Mr. J. B Simpson, a local coal-owner, as a memorial of his late father. The institution will be known as the "Robert Simpson Memorial Homes for Aged Miners." The relations between capital and labour in this district ought certainly to be most amicable, and if the large sums of money which are so constantly being given for charitable purposes be any indication they must be so, notwithstanding the ill advised strikes which do so much to cripple the best friends of the employed—the capitalists.

A Sign of the Times.

Miss Norah Kemp, M.B., C.M., has entered upon her duties as *locum tenens* for the assistant medical officer at the Northumberland County Lunatic Asylum at Morpeth.

Aug. 31st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Aboyne Hospital Site Question.

THE Local Government Board has declined to interfere as to the proposal to change the site of the fever hospital now being erected at Aboyne, Aberdeenshire, on the ground that no guarantee has been given for the extra cost (upwards of £2000) involved. The Marquis of Huntly, however, has addressed a representation to the Local Government Board in favour of a new site, but as the roof is now on the buildings in progress his objection will probably end in nothing practical. Lord Huntly contends that the demands of the county medical officer are extravagant, and that the cost of removal to another site need not have exceeded £1000, the sum guaranteed by Sir W. C. Brooks, Bart., of Glen Tana.

Aug. 31st.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Local Government Board and the Mitchelstown Union.

SOME months ago the board of guardians of Mitchelstown Union appointed a Mr. Lagherty, clerk of the works, in connexion with the erection of a dispensary residence for the medical officer at Galbally at a remuneration of £1 per cent. on the necessary outlay. The guardians subsequently brought an action against him to recover £500 for negligence and non-fulfilment of his contract. This not alone failed but resulted in the former being condemned to pay the defendant's costs—viz., £60. During the trial it moreover transpired that the defendant at the time of his appointment was eighty-three years of age and was by trade a carpenter. The Local Government Board have now notified their intention to seize the workhouse in consequence of the action of the guardians, chiefly in reference to their non-payment of this bill of costs; and the position of the union is rendered critical by the fact that the guardians have been already surcharged by the auditor of the Local Government Board to the amount of £123, while further heavy surcharges in connexion with the dispensary house are pending. At a specially convened meeting of the guardians held on Aug. 28th, a resolution was passed requesting the Local Government Board to permit a cheque to be passed for the amount of the bill of costs irrespectively of other matters in dispute. There seems to have been some grave irregularity in the procedure adopted by this board of guardians recently, and as a consequence the completion of the much required dispensary residence at Galbally is likely to be long delayed.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Moscow Congress.

MOST of the learned societies are taking a holiday, and the two which continue to sit—namely, the Academy of Medicine and the Academy of Sciences—have received no communication of importance, all the interesting papers having been reserved by their writers for the Moscow Congress. The daily press is full of matter about this meeting. As a rule the French members of the Congress express great regret at the insufficient organisation in France preparatory to the Congress. Relatively few members have attended from France, especially among the prominent medical men attending the Congress, and it is certain that the Germans, being nearer the scene of the Congress, have attended in greater numbers. It is especially to be regretted that military medicine had only one French representative and nearly a hundred German. The excessive cost of the journey, due mainly to the fact that Germany refused any reductions to foreigners going to Russia, is partly accountable for the scarcity of French members.

Holothyrus Coccinella.

M. Mégnin recently showed before the Academy of Medicine a parasite of a fairly large size which had been sent to him from the Mauritius by Dr. Charmoy for the determination of its zoological position. It is the Holothyrus coccinella of Gervais. Its popular name is "Trouille canard," and poultry farmers know its noxious properties so well that they have given up breeding birds in those elevated and damp regions of the island where this parasite abounds, lying hidden during the day under the moss and stones. Even children have often fallen victims when, having found a "trouille canard," they have put their fingers in their mouths after having touched it, for the tongue and pharynx become affected with an exceedingly painful swelling, so that they are in danger of asphyxia. With his last consignment of these parasites M. Mégnin tried some experiments to verify the existence of these unheard-of properties. If one is applied to the skin and kept there by a bandage a burning sensation is felt which after a time becomes very disagreeable, although the skin is only slightly œdematous and exhibits no change of colour. Upon mucous membranes the effect is very much more pronounced.

The Control of the Hospices in the South of France.

The General Council of the Bouches-du-Rhône have adopted a resolution for laicising the Hospices, which has been accepted by the Administrative Commission of the Hospitals, and the municipal council has made itself responsible for the sum of 45,000 francs, which will be the probable increase in the expenses caused by the suppression of the nuns. The prefect, considering that this sum will not be enough, has not yet approved the idea. M. Charles Roux voted against the proposal, not because he had any scruples as to the laicising, but because he considered the 45,000 francs would not be enough to provide for the new organisation, and before making any change it would be better to increase the number of beds, which are now so notoriously deficient that, as he says, every day more than twenty patients are refused admission at every hospital in Marseilles.

The Bacteriological Laboratory.

The total number of diagnoses made at the bacteriological laboratory of the Prefecture of the Seine during July, 1897, was 183. Of these 122 were diagnoses of doubtful sore-throats, and in 24 of them Löffler's bacillus was found, which brings the percentage of diphtheria observed during the month to 19·6. These figures are higher than those (namely, 18·1 per cent.) which obtained during the month of June, and the increase is entirely due to a short-lived rise in the number of cases of croup observed during the first fortnight of July. In the second fortnight of this month the number of cases of sore-throat underwent a marked diminution. Of the remaining cases sent up for diagnosis 47 had reference to suspected tuberculosis, and in 17 of them Koch's bacillus was discovered.

The late Dr. Jules Bernard Luys.

Dr. Jules Bernard Luys, the eminent alienist physician, Member of the Academy of Medicine and Officer of the Legion of Honour, has just died suddenly in his sixty-ninth year at Divonne-les-Bains (Ain), where he was passing the summer with his family. Born in Paris in 1828, resident medical officer at the hospital in 1853, and graduated as M.D. in 1857, Dr. Luys became in 1862 physician to the Salpêtrière and the lunatic asylum at Ivry (Seine). His researches were more particularly devoted to the study of the structure and disease of the cerebro-spinal nervous system, and his numberless writings have spread abroad his theories throughout the whole scientific world. He is credited with the discovery of two portions of the grey matter before undescribed, to which has been given the name of corpora Luysii. His best-known work, "The Brain and its Functions," was published in 1878. Dr. Luys was for a long time professor at the Salpétrière, afterwards at the Charité, where he devoted himself specially to the study of the phenomena of hypnotism. To support his ideas on this subject he published two books, "On the Emotions in Hypnotics" and "Clinical Lectures on the Principal Phenomena of Hypnotism." Lately the scientific world followed with the deepest interest some curious experiments of Dr. Luys relative to radiography—that is to say, photography of the "effluves" of the human body, an account of which was given in my letter published in THE LANCET of June 12th, 1897 (p. 1641).

ROME.

(FROM OUR OWN CORRESPONDENT.)

Typhoid Fever at Milan—a Warning.

FOR a month and more the Lombard capital has been a prey to typhoid fever, which may be said to be almost endemic within its walls. My last reference to the fact[1] indicated rather the wide diffusion than the intensity of the malady; now I learn on authority that, while its area is extending, the cases "assumono nella maggior parte forme piuttosto gravi" (assume for the most part rather grave features). Indeed, Milan, in city and suburb, is face to face with a very serious recrudescence of one of her generally latent, never absent, scourges, shown in the increasing typhoid fever admissions into her Ospedale Maggiore, whose many wards are all "piene zeppe" (full to bursting) with cases. At the city gates matters are not a bit better. At Sesto di Monza, for instance, there were on the 24th inst. more than 100 cases including those in hospital and those under treatment in their own homes; while further afield, in the country districts, the malady is as severe as it is widespread. These facts must give pause to the tourist world, which will soon be on the wing, and which, after a brief sojourn on the Alpine levels or at the lakes, is wont to use Milan as a halting-place before resuming its southward flight. If that great *entrepôt* of travel finds itself shunned this autumn, or, indeed, till it can honestly publish a clean bill of health, it will have only itself to thank. "Acqua inquinata" (polluted water) is the nursing mother of typhoid fever, and until the wealthiest of Italian cities has the public spirit to provide itself from the not too distant Alps with a pure and abundant supply of that necessary it must expect the stranger within its gates to be (as Americans say) "a stranger some more." Nestling in the Lombard plain, Milan has far too long, or far too exclusively, relied for her drinking-water on wells sunk in the subsoil, and it is high time that she should follow the example of her much poorer sister, Naples, whose Serena aqueduct is at once salutary to her health and creditable to her enterprise. Not that Naples makes the most of her advantages. Water otherwise excellent she allows to be contaminated with impurities from public baths or worse, and as a consequence I am told that in the Pizzofalcone barracks an epidemic of typhoid fever has broken out in the 10th Regiment of Bersaglieri, of whom over a hundred are now in hospital.

An Odyssey under Quarantine.

"Pazienza!" sighs the Italian where the Englishman clamours for "reform"; and certainly Italy acquiesces in abuses and grievances which in the British Isles would scarce survive a sitting of Parliament. Quarantine as enforced at Italian seaports is an instance in point, the latest victims to its formalities being four distinguished Italians themselves, with whom, as with most Englishmen, "time" is indeed "money." Professor Lustig, Dr. Malenchini, Dr. Galeotti, and Dr. Levi, all members of the Florentine Medical School, sent by the Di Rudini Government to Bombay, there to study the plague and the best means of preventing it, had returned, on the completion of their task, as passengers in the *Britannia*, which unfortunately had on board three Hindoo stokers or firemen all down with Asiatic cholera. On nearing Brindisi, the health conditions of the liner becoming known, "libera pratica" (free course) was denied it and the passengers were prevented from landing. Meanwhile, a party of Florentines had come all the way to welcome their returned kinsmen, but were told they could not approach the compromised vessel. In vain were protests raised by the passengers whose voyage terminated at Brindisi that at least they might be landed in Italian waters and accommodated for the statutory time at the not distant Lazzeretto Alberoni di Venezia. They were not only compelled to remain on board, but to pursue the ship's voyage to London. So in spite of themselves some fifty passengers, including the four Tuscan pathologists, had to test the virtues of "Pazienza" and go on to the British metropolis, thereby postponing the welcome and the business awaiting them in Italy from the third week of August to the first week of September. The Italian press is indignantly asking for what purpose marine sanitary stations like the Lazzeretto Alberoni di Venezia are maintained if, in circumstances like those referred to, they cannot be utilised. Well indeed it may. But Italians must be reminded that their own legislation is chiefly responsible for the enforcement of quarantine in the Mediterranean and that the English-speaking world for generations has had to sacrifice even more valuable time than theirs by the perpetuation of formalities at sea which should long ago have gone the way of "sanitary cordons" on land.

Dr. Maurizio Sacchi.

The fate of this young and gifted nature-student is still one of the dark problems of what (for Italy at least) I have called "the doubly Dark Continent." He was, it may be remembered, the surgeon and medical adviser of the ill-starred expedition under Captain Bottego and was believed to have escaped the massacre that befel all but two of his comrades by the accident of his having been sent, just before the catastrophe, on a special mission to the coast. Now it is surmised that on his return journey, presumably to rejoin the main body whose destruction was unknown to him, he himself was murdered. Doubt, however, has

[1] THE LANCET, Aug. 7th, 1897.

Digitized by Google

been thrown on this conjecture — for it is imperfectly supported by facts—and now I hear that from his native Mantua a traveller has offered to go in quest of him if alive, or of his remains or of details concerning him if dead. This volunteer is no other than the intrepid African explorer, Signor Emilio Dal Seno, who in July, 1893, was rescued from a savage prison in Lugh by poor Captain Bottego in person. The Società Geografica Italiana is deeply interested in this quest, for it is known that Dr. Sacchi had amassed much novel and valuable information (including specimens of the flora and fauna), not only in the natural history, but in the geographical and meteorological features of the country between Lake Rodolfo and the seaboard.

Aug. 28th.

MONTREAL.

(FROM OUR OWN CORRESPONDENT.)

The Royal Victoria Hospital.

THE third annual report of this hospital has just been issued. It is an interesting pamphlet of ninety pages, and gives more information than is usually furnished in annual reports. It gives a brief epitome of the more important cases observed and treated. This splendid institution, founded and endowed by Lord Mount-Stephen and Lord Stratherna and Mount Royal of Glencoe, has an income from capital of £11,000, but this is not sufficient, as the expenditure for the last year was £16,000. With an average of 167 beds occupied daily, the expense represents 5*s*. 9*d*. per patient per day. Of the 2016 patients treated 50 per cent. were Protestants, 44 per cent. Roman Catholics, and 6 per cent. of other faiths. Of the adults there were 912 males and 908 females; and the children under twelve years of age numbered 196. The total mortality was 5 per cent., a not unusual rate for a general hospital. Bathing is favoured for typhoid fever. Of 68 cases of typhoid fever 47 were given baths; the number of baths varied from 1 to 79, and averaged 28. All the patients recovered. In 78 per cent. there was manifest eruption, and in 66 per cent. the spleen was palpable. The febrile period existed from three days to eighty-four days, the average being twenty-four days. Diarrhœa was present in 8 per cent. of the cases and constipation in 91 per cent. Baths were given every three hours when the temperature remained over 102° F. The patient was immersed in water at 90°, and the water was rapidly cooled to 80°. Later, colder water was used, down to 65° in some cases. On the surgical side there were 77 cases of appendicitis with 5 deaths. Appendectomy was performed 58 times, but the mortality is not given. In the gynæcological department there were 53 cœliotomies, with 1 death. The one death occurred in a case of abdominal hysterectomy. 8 other cases of abdominal hysterectomy and 11 vaginal were successful. Ventro-fixation of the uterus was done 28 times, with 27 recoveries and no deaths. In the eye, ear, nose, and throat department there were 176 patients, with 1 death, and this one died from diabetes. In the pathological report a case of septicæmia is noted, with bacillus aërogenes capsulatus and emphysema of the spleen.

Variola.

The city has been free from small-pox since the great epidemic of 1885–86. In July of this year a case developed, but the source could not be traced; since then 13 cases, with 4 deaths, have occurred; in the west-end suburb of Westmount 4 cases occurred, with 1 death. The health authorities have been stirred to great activity by the outbreak, and as but one infected house now remains under supervision, it is hoped that the worst is over. The difficulty, arising from divided control of the Civic Infectious Diseases Hospital referred to in a former communication has been surmounted by giving the entire control of the institution to the medical health officer, Dr. Laberge. The building itself is in very bad condition, but hurried repairs have been made in the portion set apart for small-pox cases. Free vaccination is performed at numerous stations throughout the city.

Lord Lister.

The visit of Lord Lister to Canada to attend the meetings of the British Association for the Advance of Science has been taken advantage of by the medical profession to do honour to one so eminent in medicine and in science. The Medico-Chirurgical Society of Montreal will entertain his lordship at dinner at the Windsor Hotel on Aug. 31st, when a congratulatory address will be presented to him, referring to his elevation to the peerage. It was intended to make the presentation some time ago, before it was known that he would be in Montreal. Lord Lister will remain in the city throughout the meeting of the British Medical Association.

British Medical Association.

Among the men of science who came over for the Toronto meeting, there were a number of medical men who will also attend the British Medical Association's meeting in Montreal. An immense programme has been prepared for this latter; the scientific features and the entertainments would be, either of them, sufficient for two conventions. The hospitality offered consists of garden parties, receptions, concerts, dinners, golf, steamboat excursions, trolley rides, masonic meetings, chess, &c. An enthusiastic wheelman, Dr. Lapthorn Smith, will take a party whose lives are insured to the top of Mount Royal at seven o'clock in the morning of Sept. 1st, to descend by bicycles a two mile route by gravitation.

Jubilee Nurses Home.

The Victorian Order of Nurses' scheme is in abeyance at present, but the authorities of the Montreal General Hospital have succeeded so well with a project for the building of an establishment for the accommodation of nurses in training and nurses awaiting calls, that ground has been broken on a site convenient to the hospital, and Lord Lister has accepted the invitation to lay the corner stone. In the management of this enterprise, it is intended to supply a part of the remuneration of the nurses from a fund, as the usual charge of 8*s*. per day, is prohibitive to many families.

Chemistry Building.

The latest addition to the group of buildings in the McGill Park is the Chemistry Building; it is nearing completion and will be in occupation during the coming season, though not at the beginning. It is a benefaction from a wealthy manufacturer, Mr. W. C. Macdonald, whose numerous contributions to the university can only be described as princely. When Sir H. E Roscoe was visiting Montreal he said in a speech that the only thing needed to complete the splendid equipment of McGill University was a special building entirely devoted to chemistry. Mr. Macdonald said it would be supplied and would be of the very best description.

Aug. 21st.

AUSTRALIA[1]

(FROM OUR OWN CORRESPONDENT.)

Vital Statistics of New South Wales.

THE annual report of the Registrar-General on the vital statistics of New South Wales shows that in the metropolitan district the ratio of deaths per 1000 of the population has in ten years declined from 20·87 to 13·18. The decline has not been uniform, but since 1890 the variation has been no more than 3 30 per 1000. The decrease is not due to exemption from infectious disease, but is ascribed to the excellent water-supply and drainage system of the metropolis. Infantile mortality still remains high. In the metropolis it is higher than in the country, and higher in the suburbs than in the city itself. North Sydney, the fashionable suburb, has the lowest mortality from all causes.

Diphtheria in Sydney.

In my last communication reference was made to the prevalence of diphtheria in the neighbourhood of Melbourne, and from a report of the medical officer to the Sydney Water and Sewage Board it appears that this disease has been very prevalent in the sister metropolis also. During the present year 123 cases had been reported and investigated. There was no appreciable difference in the number of cases between the sewered and unsewered districts, and the idea of any connexion between the disease and sewers is discountenanced, and the cause is more probably to be sought in the imperfections of ordinary domestic sanitation. Many of the dwellings in which the disease made its appearance were very dirty and showed gross signs of individual neglect. Fowls were kept in small yards and allowed to remain about the houses. The aggregation of children in schools under faulty sanitary conditions is regarded by the medical officer and the Board as one of the most potent agencies in spreading the disease. The milk supplied to the various reported

Digitized by Google

cases came from all parts of the country, and it would be impossible to charge any particular supply with disseminating the disease. One of the reported cases, however, came from a milk shop, and the sale of milk was allowed to continue even after the existence of the disease had been established beyond all doubt. Great stress is laid on the necessity of a stricter supervision of the milk-supply.

Supervision of Milk Supply in New South Wales.

This subject has been receiving a good deal of attention from the health authorities in New South Wales lately, and has evoked a long correspondence in the Sydney press. The Richmond River district has recently risen into importance from the extent of its dairying industry, so that the Dairies Supervision Act has been administered in it only by local authorities. For a few months past the veterinary inspector of the Board of Health has been supervising the local authorities in their duties under the Act, and has had to require many alterations, involving outlay of money. This interference has been resented by the dairymen thus compelled to abandon their happy-go-lucky methods. The President of the Board of Health has insisted on the necessity for the adoption of the most rigid precautions by dairymen to ensure the purity of the milk-supply, and especially for inspection of the dairy herds by veterinarians to see that they are free from tuberculosis. In this view he has been supported by the leading medical practitioners in Sydney, though some statements as to the frequency of tubercle in children have been challenged. The press has also strongly advocated rigid inspection of all dairy herds, the general use of tuberculin as a diagnostic agent, and the destruction of all tuberculous and diseased animals, while the price of milk must be raised proportionately.

Presidential Address.

Dr. A. A. Lendon, the retiring President of the South Australian Branch of the British Medical Association, in his address, dealt more particularly with the subject of the federation of the different Australian medical societies. He advocated that the colonial branches should be grouped into a division of the British Medical Association, and that to this Australian division the Council should grant a greater degree of autonomy. A divisional or federal council should be established (in part elected by the branches, in part nominated by the Council) which should elect members of the Association in Australia, and have power to expel members and to create new branches. This Australian Council would be directly represented on the London Council, and the necessary funds would have to be provided for by a rebate on the subscriptions at present forwarded to London. Such an arrangement, in Dr. Lendon's opinion, would really strengthen the ties between the present Association and its numerous colonial offshoots and is perfectly feasible. There is, I am aware, a growing dissatisfaction among members in the colonies at the present arrangements, especially as regards unattached members and powers of expulsion of members, and the troubles in Adelaide over the hospital and the action of the London authorities with reference to Dr. Napier and Dr. Smith have served to accentuate this feeling in some measure. The question of the amalgamation of the various societies into one body was ventilated at the last meeting of the Inter-colonial Medical Congress, but did not seem to meet with much approval.

Dinner to Sir Thomas FitzGerald.

On July 22nd the medical profession in Victoria entertained Sir Thomas FitzGerald at dinner, in commemoration of the honour of knighthood recently conferred on him. The gathering was thoroughly representative and most enthusiastic. Dr. Neild, who presided, said it was the largest medical dinner, the most unanimous, and the most representative he had witnessed during an experience of over forty years in the colony. The honour conferred on the guest was exceptional, in that it was the first time in the Australian colonies an honour of the kind had been conferred on a medical man purely and solely on account of his professional eminence. Sir Thomas FitzGerald, by his scientific attainments and rare merit, had raised himself to such a position as to thoroughly deserve the dignity. He asked the company to drink Sir Thomas FitzGerald's health and long enjoyment of his title in a spirit of brotherhood, and the toast was drunk with the greatest possible enthusiasm. Sir Thomas FitzGerald, on rising to respond, received a tremendous ovation, the whole company rising, waving their handkerchiefs, and cheering vociferously. Speaking with considerable emotion Sir Thomas FitzGerald said he hardly knew how to express his feelings. He had always tried to do his best to advance the profession, and he could honestly say that he had never wittingly been guilty of a breach of professional etiquette. He wished to do all he could to elevate the profession, and for this reason he had accepted and welcomed the honour, not as a personal, individual compliment, but as an incentive to the profession, which was thus honoured through him as a member of it, and he trusted he would not shuffle off this mortal coil before he had the pleasure of seeing several of his friends similarly honoured. He then gave some reminiscences of his early struggles, and concluded by thanking the gathering for the very great compliment they had paid to him. The staff of the Melbourne Hospital then presented him with a handsome illuminated address worded as follows :—

"Sir Thomas Naghten FitzGerald, Knight, F.R.C S.I., Surgeon to the Melbourne Hospital; President of the Inter-colonial Medical Congress, 1889.

"DEAR SIR THOMAS,—Upon the auspicious occasion of your knighthood at the hands of Her Most Gracious Majesty the Queen in connexion with the sixtieth anniversary of her glorious reign, we, your colleagues on the staff of the Melbourne Hospital, welcome the opportunity of offering you our warmest and most sincere congratulations. Your term of office amongst us is the longest in our annals. The fertility of your conception and the brilliancy of your operations have shed a lustre upon the institution which we all delight to serve, and directed as they have ever been by a high sense of professional honour they have won for you the esteem and affection of every member of the staff, the admiration and respect of successive generations of students, amongst whom more than half the present staff are proud to number themselves, and the veneration and confidence of innumerable hosts of patients. We thus look upon your official recognition, not only as a deserved, although long delayed, honour to the profession generally, but as conferred upon one of whom the practically unanimous verdict of his fellow practitioners throughout Australasia would have been given as 'of all the most worthy.'"

Sir Thomas FitzGerald, in replying, said he loved the hospital and he loved the staff, and he thanked them most sincerely. An address of congratulation was then presented from the Ballarat District Medical Society, and Mr. Gaffney conveyed the congratulations of the profession in Bendigo. During the evening songs were contributed by several members of the profession, and the proceedings closed with a vote of thanks to the chairman.

An Epidemic of Pemphigoid and Furuncular Skin Disease due to a hitherto undescribed Micrococcus.

At the last meeting of the Medical Society of Victoria Dr. James A. Reid contributed a paper in which he described a series of cases of skin affections characterised by bullæ, lymphatic inflammation, boils, and vesicles. In all the cases a definite micrococcus was found on bacteriological examination. It generally occurred as a diplococcus, liquefied gelatin, and was actively motile. It was aerobic and facultatively anaerobic, and pathogenic to man, mice, and guinea-pigs. Injections of pure cultures into mice and guinea-pigs caused abscesses the pus from which contained the same organism. Dr. Reid can find no previous description of a motile pathogenic micrococcus. Demonstrations were given of the organism in various culture media.

Death of Dr. Cutts.

The news, received by cablegram, of the death in London of Dr. William Henry Cutts came as a shock to his friends here. Dr. Cutts used to be a very prominent figure in the medical world of Melbourne, where he practised as a physician for many years and was very greatly respected. He came to the colony in 1852, and was shortly after appointed honorary physician to the Melbourne Hospital, a position he held for seventeen years. He was also for many years a member of the Council of the Melbourne University. He assisted in founding the Medical Society of Victoria and the *Australian Medical Journal*. Later he helped to found the Victorian Medical Benevolent Society and the Victorian Branch of the British Medical Association, of all of which he was at one time or another president.

July 24th.

Obituary.

CLAUDIUS FRANCIS DU PASQUIER, F.R.C.S. ENG., L.S.A. LOND.

CLAUDIUS FRANCIS DU PASQUIER was born in London on Nov. 23rd, 1811. His father was a native of Neufchatel.

Digitized by Google

He received his education at Mr. Pollard's, Blemill House, Brompton, and subsequently was bound at the Apothecaries' Hall and served his apprenticeship to Mr. John Nussey, of Cleveland-row, St. James's. In due time he became a Licentiate of the Society of Apothecaries and passed the examination for the Membership of the Royal College of Surgeons. He then had the appointment of assistant apothecary to St. George's Hospital, where he remained between two and three years, when he was admitted into partnership with Mr. Nussey. Mr. Du Pasquier was appointed surgeon-apothecary to Her Majesty in 1862, having already attended the late Prince Consort as apothecary. Later he became surgeon-apothecary to the Prince of Wales's household. After being in practice for forty years he retired from the profession and went to reside at Norwood.

An old friend, Mr. Edward Tegart, writes the accompanying lines:—"The late Mr. Du Pasquier deserves more than a mere formal notice because he was so excellent a representative of that class which socially is so important, the trusted family adviser. A gentleman in feeling and conduct, incapable of anything ungenerous or unhandsome, he was one in whom thorough confidence could be placed. With his sensitive disposition he shrank from seeking the prominent position which he might have taken, but those who knew him best valued him all the more. He had resources in himself besides his profession, and was especially fond of natural history pursuits and gardening. He had retired from practice many years before his death; indeed, his health required this. From his advanced age he has survived most of his old friends, and those who remain will think of him with affection and regard. I had known him intimately for so long that I deem it a duty to offer my tribute to his memory."

Mr. Du Pasquier died at his residence, Upper Norwood, on Aug. 20th, in his eighty-sixth year. He married the youngest daughter of Mr. John Bidwell, of the Foreign Office, who survives him. During the years he was in practice he lived at 62, Pall-mall, and was for some years on the court of the Society of Apothecaries, of which he was offered the mastership, an office he declined. He was always proud of having been a fellow-student of Sir Prescott Hewett, with whom he kept up a great friendship. During his later years he suffered frequently from attacks of eczema. He had been failing very much in health for the last year or two and had become very feeble during the last few months. A week before his death occurred he had to take to his bed owing to a slight gouty attack, from which he never rallied.

HENRY VINCENT GARMAN, M.R.C.S. ENG., L.S.A. LOND.

THE death of Mr. Henry Vincent Garman, at the age of seventy-three years, took place on Aug. 25th. Mr. Garman was one of the oldest and best-known practitioners in East London, having held, besides several other appointments, that of police surgeon at Bow for the very long period of forty-six years. He had not been in active practice for the last five years.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men have been announced:—Dr. Holmgren, Professor of Physiology in the University of Upsala, died suddenly from a cardiac affection on Aug. 14th. He was born in 1831, and worked for many years under Brücke, Du Bois Reymond, and Helmholtz. He was appointed to the chair of Physiology in 1864, and had the honour of establishing the first physiological institute in Sweden. He was chiefly known in this country from his researches on colour-blindness and his plan of testing the colour sense by means of wools.—Dr. T. Bogomoloff, Professor of Medical Chemistry in the University of Kharkoff, at the age of fifty-four years.—Dr. Franz Walser, *privat-docent* of surgical operations in the University of Gratz.—Professor Carl Liebmann, a well-known gynæcologist of Trieste.—Dr. Guardia, formerly Assistant Librarian of the Paris Academy of Medicine.—Dr. Gros, Professor of Clinical Medicine in the Algiers Medical School.—Dr. Enrique Moresco y Larado, Professor of Children's Diseases in the Cadiz Medical School.

THE TWELFTH INTERNATIONAL MEDICAL CONGRESS.

MOSCOW, AUG. 19TH—26TH.

THE Congress came to a formal conclusion on Friday, Aug. 27th, but many members had already left Moscow, being unprepared for the wave of tropical heat which spread over the city during the week. Indeed, so early as Monday, Aug. 23rd, but two clear working days after the opening of proceedings, as many as a thousand members returned to their homes, or started on one or other of the various excursions.

The crowding, however, did not visibly decrease, so very excessive has the number of members been in proportion to the accommodation provided by the resources of the city. It is doubtful whether the great crowd of 7000—and some put the total figure at nearly 9000—have been really and genuinely medical men. There was no scrutiny made of the demands to be enrolled as a member. The form had to be filled up and returned to the General Secretary with a guinea or its equivalent and the rest followed. Now to all dwellers upon or near the frontier who became enrolled the Congress presented an excellent opportunity for sight-seeing and a cheap holiday, for to them the free passes to and from Moscow meant a vacation free of travelling expenses. Consequently, there is no doubt that a large number of persons only indirectly connected with the medical profession availed themselves of the advantages going begging for one guinea, and have swelled the numbers of the Congress without a corresponding addition to the deliberative wisdom of the assemblies. To English and American people there has been no temptation to visit Moscow to make a cheap holiday, as the total distance to be travelled made the gift of a free ticket for the last 450 miles no very serious inducement.

The work in the sections was lightened by the tropical heat. Flesh and blood could not stand many long hours of confinement in crowded rooms, however large, with a thermometer persistently above 88° F. in the shade, and as a consequence the proceedings were got through with an expedition that was more due to absence of debate than to any great precision of arrangement. In some cases this was to be regretted, as many valuable and interesting communications, which might well have provoked comment, have fallen quite flat, and we must await the publication of the special records of the Congress for the rescue of these papers from oblivion.

The heat did not, however, deter the members from making the different excursions with vigour and determination. Of these there were several to choose from, as the officials had organised expeditions all over Russia, in Europe from St. Petersburg to Sebastopol, and from Nijni Novgorod to Odessa. But next to the Sparrow Hills, only a few miles away from Moscow, far the most popular excursion was the one to Nijni Novgorod, where the great fair was in full swing. The great fair is no longer what it was when Laurence Oliphant made us all long to see it. Then it was the great meeting-place of the producers of the coarse material coming from the east and the wholesale merchants coming from the west. Now the salesmen are the western shopmen who take to Nijni Novgorod the manufactured articles for sale into the more outlandish east. As a consequence the fair has lost much of its ethnological interest and all its picturesqueness. It is a very big and very dusty bazaar, full

Digitized by Google

of tin pans, bad *ikons*, and ugly American cloth. There are other articles on sale, but these and cheeses predominate.

Many of the English-speaking people in Moscow wondered at the absence of all attempt to organise an English-speaking bureau, where information might be obtained, and it was very generally felt that the English committee ought to have done something for the convenience of their brethren. It was comparatively easy work for any clear-headed man with a working knowledge of French or German to acquire a very good idea of the trend of the proceedings of the Congress. But every Englishman does not speak French or German, and every man away from his home is not as clear-headed as he is in his usual environment. To these a bureau, where during, say, one hour in the morning and one hour in the evening they could apply for ordinary information concerning *wagon lits*, passports, postage rates, excursions, &c., would have been of the greatest possible service, and we cannot understand why such a bureau was not organised. Sir William Mac Cormac was presented to the Czar as the representative of the English Committee, and there all the work of the committee stopped. Sir William Mac Cormac would have greatly obliged some of his humbler brethren if he had brought to bear his well-known powers of organisation for their convenience. In England the whole burden of organisation fell upon Mr. G. H. Makins, and, as everyone knows, he discharged his thankless task admirably. Some other members of the committee might have been found to continue the work in Moscow.

For Moscow is not like Rome, Berlin, Vienna, Paris, or St. Petersburg, where many people know a little English, and all have a smattering of some other tongue than their own. Moscow is Russian to the core, and only Russian is spoken, so that the need for a little help was felt by many of the English-speaking members, hardly one of whom knew six words of Slav. Moreover, all the official notices were freely printed in German and Russian and occasionally in French, but never in English. This was perhaps as well if the Russians were to depend on their own efforts and not to employ an English translator, as the following extract from a circular addressed in the official journal of the Congress to all members in their own tongue will show:—

"NOTIRE.

"In commemoration of the XIIth International Congress of Physicians in Moscow, there will be edited an elegant album of photographs of the Members of this Congress, with short biographical notices & facsimiles of each. This album is intended to be presented to the Imperial Protectors of the Congress—His Imperial Majesty, the Emperor Nicolas II and H. I. H. the Great Duke Serge Alexandrowitch.

"The album will contain besides photographs a wiew of the monument of Pirogoff, of the Moscow Clinics & the best views of the town.

"S take therefore the liberty of inviting yon dear zir, to favour me with your visit at my artistical installation to the effect of being graciously photographed, or to lit me kindly hane a portrait of yours whereof S could take a copy. Price of the album be Rs. 5. My adress is noted at the head of this. The installation is oper: the days of Congress from 8. o'clock in the morning untill the evening; all ather days from 10 to 5. in the afternoon."

In particular members would have been glad of information concerning the police formalities to be complied with before leaving the country, for the notices issued were contradictory in the extreme, members being told in one breath, firstly, that all passports must be *visé* at the *chef du police*, and secondly, that in the case of *Messieurs les Congressistes* such formalities were unnecessary. Detention on the frontier was a possibility which it was difficult for those who had made other and definite plans to contemplate with equanimity.

But if the English-speaking members were not helped by any committee, they were helped as far as possible by their thoroughly genial and kindly hosts. In every direction, and from top to bottom of society, the desire to make the twelfth Congress a pleasant recollection in the minds of its members has been obvious. And pleasant that recollection will be in most cases we are sure, for Moscow is above almost all cities in the world one whose panorama can be carried away in the eye—it is so simple and yet so gorgeous. And if any member in reverting in his mind to this Congress should be inclined to dwell upon delays at railway stations, hard and not altogether lonely beds, or extortionate drivers of *droschkys*, let him close his eyes and call up reminiscences of the quaint unnatural beauty of the Church of St. Basil, the lavish gleaming magnificence of the Cathedrals of the Annunciation, the Assumption, and the Archangel and the gilded cupolas of the bell tower of Ivan Véliki, seen against a background of azure sky, or green roof, or cobalt tower, or chocolate wall, then will he conclude that the little hardships were as nothing compared to the benefits that accrued to him during his sojourn in Holy Moscow.

THE SECOND GENERAL MEETING.

The second general meeting of the Congress was held in the Grand Opera House on Sunday, Aug. 10th (22nd), at two o'clock in the afternoon. The theatre, which is said to be capable of seating between three and four thousand people, appeared to be filled to its utmost capacity. The stage, as before, was occupied by the office-bearers, official delegates, and distinguished members of the Congress. Immediately preceding the general meeting a special meeting had been held, at which only the presidents of sections and presidents of national committees had been present, in order to discuss the question of the place of meeting of the next International Congress. At this smaller gathering, at which some eighty persons were present, invitations were received from the representatives of France and of Spain, and the choice lay between Paris and Madrid as the scene of the Thirteenth Congress. By a very large majority it was ultimately decided to accept the French invitation. The decision appeared to cause general satisfaction, as the next Congress will coincide with the great exhibition to be held in Paris in 1900, just as the first International Medical Congress coincided with the first Paris Exhibition of 1867. Professor LANNELONGUE (Paris) having been elected President of the next Congress, he was asked to take the chair at the second general meeting of the present Congress on Sunday last. The first address at this meeting was read by Professor KRAFFT-EBING (Vienna), whose subject was the Etiology of Progress in Paralysis. Professor Krafft-Ebing, who spoke in German, dwelt at some length upon the influence of contemporary social conditions on the human nervous system. Never before, he said, had so severe a demand been made upon the mental faculties as in the present century. Never before our own age, which might well be called the Nervous Age, had the brain been called upon to receive so many new, involuntary impressions. Social and political changes, the struggle for existence, increased facilities of travel and communication, and the competition inseparable from modern conditions of life, had all thrown a great strain upon the nervous system. The agriculturist had been driven to the town, where he lived under unhygienic conditions; the small tradesman and artisan had been crowded out by the large manufacturers. And this struggle for existence had told, not only on men, but to a considerable extent on women also. To these influences must also be added the growing use of alcohol, and the political changes which had substituted for the old patriarchal *régime* the government of the people by themselves. After a brief description of the symptoms of progressive paralysis the lecturer stated that the almost invariable cause of the disease was syphilis. Syphilis and progressive paralysis had both increased with the growth of civilisation, and it was a duty which Governments owed to their subjects to use every effort to combat the scourge. No age was exempt from the danger. The disease, which formerly attacked persons about the age of thirty-nine or forty years, now appeared in subjects at a much earlier

Digitized by Google

age. There are certain classes of the population, Professor Krafft-Ebing added, which appear to be specially liable to it—such, for instance, as labourers and officers in the army, while other classes seem to be peculiarly exempt from it. In conclusion, he expressed a hope that the necessary measures would be taken to check the growing evil.—Professor SENN (Chicago) then read an address on the Classification and Surgical Treatment of Acute Peritonitis.—He was followed by Professor METCHNIKOFF (Paris), who received quite an ovation from the audience. The title of Professor Metchnikoff's address was simply "Sur la Peste," and it was devoted principally to an interesting account of the recent work done in the bacteriology of plague. The lecturer briefly recapitulated the history of the discovery of the bacillus of plague and the mode of preparing the antitoxin. The work of Roux and Yersin was fully described. Roux had obtained the virus of plague in pure cultivation, and by immunising animals with this virus was able to obtain an antitoxin from the blood of animals so immunised. The horse was the animal usually selected. Even a weak serum had considerable effect in reducing the mortality from plague. Prophylactic injections had also proved to be of real value. In conclusion Professor Metchnikoff warmly protested against the attacks which were sometimes made upon science. Science was far from regarding with indifference the disappearance of the weakly in the struggle for existence. On the contrary, the most recent and most brilliant discoveries in medicine had shown that science, and science alone, could aid and protect the weakly in this struggle. Professor Metchnikoff's address was loudly applauded.—The meeting was brought to an end by Professor ROBERT'S address on the Characteristics of Human Pathology and its Relations to Therapeutics.

The Subscription Banquet.

A dinner for members of the Congress, at a charge of five roubles a head, was held on Wednesday evening, Aug. 13th (25th). The dinner was held simultaneously in four different places. Sections I., II., VII., and XV. dined at the "Cercle du Commerce"; Sections III., IV., V., VI., VIII., XIII., and XIV. at the "Cercle des Chasseurs"; Sections IX. and X. at the "Grand Hôtel de Moscow"; and Sections XI. and XII. at the Hermitage Restaurant. A very fair dinner of five courses, coffee, and "one glass of champagne," was provided. The dinners were attended by a considerable number; the proceedings were quite of an informal character. At the "Cercle des Chasseurs" Professor Virchow proposed the toast of "The Emperor," and a few other toasts followed. The dinner began at 6 o'clock, and by 9 o'clock most of the guests had dispersed.

The International Prize, Instituted by the City of Moscow.

On Saturday, Aug. 9th (21st), a meeting was held of the honorary presidents and presidents of sections under the presidency of Professor Sklifosovski. At this meeting a committee was elected to consider the conditions of the prize which the municipality of Moscow has offered to commemorate the holding of the Twelfth International Congress in Moscow. The committee elected was constituted as follows: M. Virchow (Germany), president; M. Fuchs (Austria), Professor Simpson (Great Britain), M. Crocq (Belgium), M. Bloch (Denmark), M. Robert (Spain), Professor Sayers (United States), M. Lannelongue (France), M. Homen (Finland), secretary; M. Pertik (Hungary), M. Romiti (Italy), M. Ogata (Japan), M. Lavista (Mexico), M. Laache (Norway), M. d'Ornellas (Portugal), M. Roth (Russia), and M. Kocher (Switzerland). The committee met on Tuesday, the 12th (24th), and has since issued the following statement:—

1. M. Roth reports that the Municipal Council of Moscow, at meetings held on June 10th (22nd) and July 29th (Aug. 10th), 1897, decided to institute a prize in commemoration of the Twelfth International Medical Congress. This triennial prize, to be awarded by successive international congresses, either for the best work upon medicine or hygiene, or for eminent services rendered to suffering humanity, will amount to 5000 francs (£200), representing the interest at 4 per cent. on the capital of 16,450 roubles voted by the municipality. The Council has also voted an additional sum of 5000 francs to be awarded by the present Congress. The municipality will decide later the conditions under which the payment of the sums named will be made.

2. M. Romiti proposed that the warmest thanks be expressed to the city of Moscow for its generous gift, and the proposal was accepted with acclamation.

3. M. Virchow proposed that at the present Congress the Prize of the City of Moscow be awarded to M. Henri Dunant for the services he has rendered to humanity in the part he has played in founding the Red Cross Societies.

4. The committee accepted unanimously the following proposal as to the method in which the prize should be awarded by future Congresses. The organising committee of each Congress will elect a preliminary commission which will collect all the preliminary data in connexion with the award of the prize. The commission, which will definitely choose the candidate to be named at one of the general meetings of the Congress, will be constituted as follows. The honorary presidents of the Congress and of the sections will meet at a special gathering summoned by the president of the Congress, and will name a member of each nation officially represented at the Congress. This committee will eventually be completed in such a manner that each section shall have at least one representative.

THE THIRD GENERAL MEETING.

Closing of the Congress.

The final meeting of the Congress was held in the Grand Opera House on Thursday, Aug. 14th (26th), at 2 o'clock in the afternoon. The theatre, as before, was crowded in every part. On the proposal of Professor SKLIFOSOVSKI, Sir William MacCormac took the chair as Honorary President of the meeting. The first address was that of Professor LUKIANOF, the Director of the Imperial Institute of Experimental Medicine in St. Petersburg, upon Inanition of Cell Nuclei. This paper contained an interesting and able account of a prolonged investigation carried out by Professor Lukianof in this particular branch of cellular pathology.—It was followed by an address by Professor LEYDEN (Berlin) on the Contemporary Methods of Treating Tuberculous Patients, and the Need of Government Control over them. Professor Leyden, who spoke in German, pointed out that tuberculosis caused more deaths than any epidemic, and that in Europe about one million persons annually fall victims to the disease. After describing the nature of the disease, and giving a brief account of its bacteriology, he said that there were two ways in which the disease might be combated. Either the bacillus might be directly attacked, or the constitutional powers of the individual might be strengthened and reinforced so as to enable him to withstand the influence of the bacilli. The efforts of Koch to produce a curative "tuberculin" were described; up to the present they could not be regarded as crowned with success. Until such an ideal curative material could be produced the best method of dealing with tuberculous patients was to treat them in specially constructed sanatoria. The principal points in this mode of treatment were the following: (1) choice of a suitable climate; (2) a good air, free from dust; (3) good nourishment; (4) exercise; (5) methodical treatment of the patient in special institutions; and (6) medicinal treatment as auxiliary to the general treatment. Cold fresh air was of the greatest importance; exercise, riding on horseback, or bicycling should also be permitted. All the various points in a successful scheme of treatment were only attainable in a properly constructed sanatorium. Many countries had already recognised the need of such institutions, and Russia had not been behind the other nations, as she already possesses three such sanatoria. Professor Leyden's address was received with loud applause.—Professor LOMBROSO, the Italian criminologist, who followed, spoke in French. The subject of his address was New Horizons and New Applications in Psychiatry. He spoke of the necessity of clear conceptions in the subject of psychiatry, not only for medical men, but for literary men, specialists in criminology and legal medicine, and for many other workers and thinkers in the field of sociology. He also discussed at some length the theory of heredity in connexion with the criminal instinct. Professor Lombroso's address was warmly applauded.—At the close of it Professor ROTH, the general secretary of the Congress, announced the conditions under which the prize of the city of Moscow will in future be awarded, and stated that the first award of the prize had been made to M. Henri Dunant, of Geneva. The thanks of the Congress were formally expressed to the city of Moscow for its institution of the prize.—Professor SKLIFOSOVSKI then spoke. The thanks of all the members of the Congress, he said, were due, first, to His Majesty the Emperor Nicholas II. for the honour he had

Digitized by Google

done the Congress in taking it under his patronage.—On the proposal of Professor LEYDEN a telegram, the text of which was read, was despatched to the Czar in the name of the Congress.—Secondly, Professor SKLIFOSOVSKI continued, thanks were due to His Imperial Highness the Grand Duke Sergé Alexandrovitch and the Grand Duchess Elizaveta Feodorovna, to whom a second telegram was also despatched. Further thanks were expressed to the Minister of Public Instruction, Count Delianof, to the University of Moscow, to the municipality, the director of theatres, the police and postal authorities, and to many others who had coöperated in furthering the success of the Congress. Finally, Professor Sklifosovski thanked the ladies' committee, the foreign Governments and institutions who had sent representatives, and all the members of the Congress, many of whom he hoped to see again three years hence in Paris. "Je ne dirai pas adieu," he said, "mais au revoir—à Paris."—Professor VIRCHOW then rose and, in the name of all the foreign members of the Congress, thanked the President and organisers of the Congress for the warm welcome they had received in Moscow and the admirable manner in which the great series of gatherings had been organised.—Professor SKLIFOSOVSKI, who was deeply touched, and whose voice was much broken by emotion, briefly responded.—Sir WILLIAM MACCORMAC, who spoke in French, made a brief closing speech. "The Twelfth International Congress," he said, "is almost at an end; its object is attained. Its success has been marked. Its labours will make an impression in the east and in the west. As regards the social and scientific gatherings of this Congress our Russian *confrères* have shown us an example which it will, indeed, be hard to imitate. They have welcomed us here, in the very heart of Russia, with all that is beautiful and all that is magnificent in this immense empire. And so we offer our most sincere and deepest thanks to our kind Russian colleagues, many of whom we trust to meet again at the next Congress in Paris."

Amidst loud applause the Congress then came to an end.

The extreme heat which set in just before the opening of the Congress has remained unbroken to the end. The last day was, in fact, the hottest of all. On Friday, the 15th (27th), the thermometer registered 94° F. in the shade at ten o'clock in the morning.

On Wednesday evening, August 13th (25th) a reception was held by the Ladies' Committee in the Salle de Noblesse, and was largely attended. The hall, a fine one, was effectively decorated with plants and flags, and a very good concert of orchestral and vocal music was performed. Madame Tairova recited a poem specially composed for the occasion, and some interesting pictures of Russian views and types of Russian character were shown on a screen by a lantern. Some national Russian dancing followed, certain of the dances being very curious and characteristic. The evening ended by the singing of the National Anthem.

SECTION I. (A, B, AND C).

ANATOMY, ANTHROPOLOGY, AND HISTOLOGY.

Considerable interest was taken in this section owing to Professor Lombroso and Professor Virchow being much in evidence. In the Anthropological Sub-division Professor LOMBROSO read a paper on the Influence of Climate on Anthropological Characteristics, and this was followed by one by Dr. ARBO on the Cephalic Index in Norway and the Difference in Form of Cranium in Different Districts in Relation to the Stature of the Inhabitants.—Professor VON LUSCHAN (Berlin) showed several Skulls with evidence of primitive trephining amongst the natives of Teneriffe.—Several papers were read on Polydactylism by, among others, Professor C. DEBIERRE (Lisle), Professor RANKE (Munich), and Professor BARDELEBEN (Jena), the question principally discussed being whether it was a deformity or a phenomenon of atavism.—Dr. WEINBERG compared the brain form of the Poles with that of several other races in neighbouring localities.—On the 23rd Professor VON LUSCHAN read a paper on the Anthropology of Certain Asiatic Races, and Dr. DENIKER on the Races of Europe. Professor VIRCHOW took part in the discussions.—Dr. IVANOVSKY (Moscow) gave some observations on the Anthropological Character of the Kurds of Ararat and also on the Characteristics of the Mongolian Skull.

Those interested in anthropology had the advantage in Moscow of having open to their inspection an extremely interesting anthropological collection, the popular character of which in some way reminded English visitors of the inimitable collection in the British Museum, though the science of anatomy was also well represented in the specimens.

SECTION II.

PHYSIOLOGY AND PHYSIOLOGICAL CHEMISTRY.

This section was not well attended, and no particularly noteworthy papers were announced.

SECTION III.

GENERAL PATHOLOGY.

There were many important papers set down for reading and discussion in this section, so many that a large proportion of them were taken as read. Professor HUEPPE (Prague) opened a debate which went to the very root of all the questions that arise in the discussion of modern pathology. His paper was entitled, "De la constance des espèces chez les microbes pathogènes au point de vue de la botanique et de la specificité des maladies." Among other papers of interest may be mentioned one by Professor LÉPINE (Lyons) upon the Genesis of Diabetes in its Different Forms; one by Professor CORNIL (Paris) upon the Pathology of Thromboses, in the preparation of which he was assisted by M. MARIE; and one by Professor BEHRING (Berlin) and Professor BOUCHARD (Paris) (represented by Professor ROGER, of Paris), upon the Rôle of the Antitoxins in the production of Artificial Immunity.

SECTION IV. (A, B, AND C).

GENERAL THERAPEUTICS, PHARMACOLOGY, BALNEOLOGY, CLIMATOLOGY, AND PHARMACY.

In this oddly-assorted section there were some interesting papers read under the different headings.

The proceedings in General Therapeutics were opened by an introductory address by Professor VON ZIEMSSEN upon the Therapeutics of the Present Day, which was listened to with the attention that the learned author always commands.—Dr. L. H. PETIT (Paris) then followed with a paper in which he advocated a prophylactic treatment of Pulmonary Tuberculosis by the establishment of sanatoria for those suffering from the disease.—Professor LEWASCHEV (Kazan) read a paper upon the Treatment of Diabetes, showing diagrams to illustrate the superiority of jambul over any other therapeutic agent.—Dr. PAUL PETRINI (Bucharest) recommended a method of feeding those suffering from the Dyspepsia of Deficient Secretion, or Atony of the Stomach, with the stomachs of cattle and decoctions made from them, and gave statistics of good results from this treatment.

Tuesday, Aug. 24th, was entirely devoted to Electricity and Electro-therapeutics.—Dr. APOSTOLI gave his recent experiences of the "undulatory current," and claimed for it that it was analgesic, that it diminished congestion, and that it was a good muscular excitant.—Professor BERGONIÉ (Bordeaux) advocated the electric treatment of trigeminal neuralgia, and also described experiments of the effects of Roentgen rays upon the bacillus of tubercle.—Dr. CHATZKY, Dr. DESCHAMPS, Dr. SASSOLI, and others also read papers upon electrical subjects.—Dr. PHILLIPS (London) was in the chair.

On Wednesday, Aug. 25th, a short *séance* was held, which was occupied entirely by a communication from Dr. PETRUSCHKI upon the Tuberculin of Koch, with notes of two cases in which it had been successfully used.

At the opening meeting of the sub-division of the section devoted to Pharmacy Professor CLAUDE VERNE (Grenoble) gave a description of his method for rendering tar entirely soluble in water, and later read an essay upon Pharmaceutical Education, strongly urging that the practical work should follow the theory and book-work, and not precede them, as at present.—Other papers were read at the two meetings upon, the Excretions of Plants, and upon some Atropine-containing Seeds, by Professor TSCHIRCH (Berne); Organo-therapeutic Preparations, by Professor POEHL (St. Petersburg); Oxydising Ferments, by Professor BOURQUELOT (Paris); while to more than one author it occurred to insist upon the formation and adoption of an international standard in pharmacy.—Professor MOELLER (Graz) recounted his recent experiments upon the Origin of Storax, which had brought him to the

Digitized by Google

conclusion that it was not a physiological secretion, but a pathological product.—Among other papers upon various drugs may be mentioned that of Dr. COLLIN (Paris) upon the Anatomical Characters of Leaves and Powders used in Medicine, and that of M. JOLCZINSKY (Moscow) upon Cheap Chinese Teas. Both these papers were of importance from the point of view of adulteration, and it need hardly be said that the adulteration of tea is a most important subject in a country like Russia, where tea is the national beverage.

On Tuesday, Aug. 24th, a paper by Professor TSCHIRIKOFF upon the best method of preparing "l'Eau d'Amandes Amers" was read in his absence.—Professor DAVIDOFF (Warsaw) discussed Ephedra Vulgaris; Dr. WARNER (Philadelphia) Ferula Sumbul; and M. KRESLING (St. Petersburg) dealt with Sero- and Organo-therapeutic Preparations from a pharmaceutical point of view; while Professor LEWIN read a communication upon Military Pharmacy.

Wednesday, Aug. 25th, was occupied by a visit to the Pharmaceutical Laboratory of M. FERREIN.

SECTION V.

MEDICINE.

Some valuable papers were also announced to be read in this section, but, contrary to the usual custom in these congresses, Medicine did not receive the same perponderating attention that it has done upon other occasions.—Professor VON LEYDEN (Berlin) read a paper on the Clinical Classification of Nephritis, in which he attempted to bring order into what is admittedly a rather disorderly subject.—Professor CELLI (Rome) discussed with intimate knowledge the theory that different forms of malaria have different parasitic origins; Professor CHARRIN and Professor GILBERT (Paris) and Dr. GRAWITZ (Berlin) read a thesis upon the Causes of Chlorosis; and Professor CARMONA Y VALLE (Mexico) and Professor RIBAS Y PERDIGÓ (Barcelona) read notes upon the Various Forms of Hepatic Cirrhosis, treating the subject from a clinical standpoint.—Dr. PAVY was invited to deliver a paper upon Diabetes.

Sir DYCE DUCKWORTH (Honorary Vice-president of the section) on Aug. 24th read a paper (in French) on Cases of Cerebral Disease in which the Function of Respiration entirely Ceases for Some Hours before that of the Circulation. He said: "The cases which I proceed to relate illustrate a remarkable point to which attention has not hitherto been much directed in clinical study—viz., the persistence of life for some hours in the absence of all respiratory effort. Such cases cannot be of frequent occurrence or they would certainly have been more fully recognised in the present day when attention is so carefully directed to the minutest clinical details. As I shall point out, however, several surgeons have observed the facts of which I now proceed to give details. I append the notes of four cases in which the respiratory function ceased for varying periods of time before death. Not to weary my audience with minute details of these, I give the following short abstracts of them: Case 1.—A girl, aged fifteen years, had suffered from purulent otitis for a year; cerebellar abscess followed. She was trephined, and pus was sought, but not found. The breathing ceased, but artificial respiration was employed *for nearly four hours* before the circulation stopped. The temperature was subnormal latterly. Case 2.—A young woman, aged twenty-one years, was admitted to hospital for headache and otitis. Respiration ceased; artificial respiration was carried on, and the skull was trephined and pus withdrawn from a temporo-sphenoidal abscess. The pulse failed, but was restored by oxygen and artificial respiration. The heart continued to beat with artificial respiration for *four and a half hours*, when it ceased. The temperature was 100·4° F. on admission on the eighteenth day, but afterwards became normal. Case 3.—A man, aged thirty-six years, was admitted to hospital with headache and otitis. Coma supervened on the seventeenth day of the illness, and on the nineteenth day the breathing ceased. Artificial respiration with oxygen and injections of strychnine were employed, and some improvement followed. The skull was trephined, and a temporo-sphenoidal abscess was tapped. The respiration ceased for *two* hours before the heart ultimately failed. The temperature varied from 96·2° to 102° F. Case 4.—A man, aged twenty-six years, was struck on the head by a heavy letter-bag in a post-office. Headache and coma followed, with left hemiplegia. The patient was trephined, and blood was removed from below the dura mater. The pulse had fallen to 44, but improved at once after the operation, but the respiration ceased and could not be restored. Artificial respiration was kept up for *five* hours before the heart stopped. A large cavity full of blood was found below the cerebral cortex. The temperature was never above normal. The patient lived for two days after the injury. Professor Macewen, of Glasgow, referred briefly to cases illustrating the peculiarity in question in his work on 'Pyogenic Infective Diseases of the Brain and Spinal Cord,' published in 1893, and in several of the cases related in this work there were observed depression of respiratory function together with a slowing of the cardiac action. In his lectures at San Francisco last year he reported cases where the pulse-rate was lowered to 40 and 20 in the minute as the intracranial pressure increased. He noted the occurrence also of modified respiration, somewhat of the Cheyne-Stokes type, in cases of abscess of the cerebellar fossa, leading to death from pressure on the respiratory centre, the pulse remaining quick and strong. In one case artificial respiration was carried on for twenty-four hours, the pulse never flagging all the time.[1] Professor Macewen informs me that he has lately met with two cases in each of which the breathing was re-established after hours of artificial respiration, and in one of these he opened and evacuated a cerebellar abscess while artificial respiration was being practised. In this case the relief of the cerebellar pressure greatly improved the general condition, and soon afterwards the respiration became voluntary. The patient recovered temporarily, dying from cardiac failure, probably due to exhaustion. The restored breathing continued perfect to the end of life. Professor Macewen has observed this phenomenon in a case of apoplexy, and in a very peculiar one, in which the brain-centre was active, but where the respiratory apparatus was destroyed by a crush, the heart continuing to beat and producing at each impulse a crackling of the broken ribs. Mr. Victor Horsley called attention to cases of this kind in a paper published in the *Quarterly Medical Journal* for July, 1894, referring to the fact that patients suffering from cerebral hæmorrhage, cerebral tumours, depressed fractures of the skull, and sudden and violent concussion, especially when applied in the occipital region, die from respiratory and not from cardiac failure, as is often supposed; and he quotes Dr. Hilton Fagge's observation that some cases of cerebral tumour and of abscess die from failure of the respiration.[2] He also points out that Leyden demonstrated in 1866 the effects of increased intra-cranial pressure in slowing the pulse, causing stertorous respiration and arrest of the latter.[3] Horsley and Walter Spencer confirmed these researches, and Leonard Hill has since re-confirmed them. Horsley's clinical studies show that in cases of cerebral tumour, hæmorrhage, and inflammatory foci death is apt to occur suddenly from arrest of the respiration, and that such is the common end of all cases of pathological intracranial tension, especially when the disease is extremely chronic. He offers the suggestion that in cases where patients fall apparently dead after sudden blows on the head, and are believed to die from cardiac failure, the real cause may be an arrest of the respiratory function, and possibly remediable by the practice of artificial respiration. Direct experiments prove that bullet wounds of the cerebral hemispheres are followed by an arrest of the breathing, and that recovery may follow when artificial respiration is employed, provided no hæmorrhagic pressure is exercised upon the respiratory centre. Again, in death by hanging the function of respiration is suspended before that of the circulation. The temperature in the foregoing cases was chiefly noteworthy in respect of the absence of pyrexia save in the third instance. The tendency in all was towards subnormal temperatures, and in the case in which the highest figure was reached there was a rise from 96·8° to 102° within sixteen hours, and operative procedures were begun at that time. These low temperatures are noteworthy in view of the several processes which were in progress within the skull. This thermic depression is, however, now well recognised in the secondary stages of cerebral abscesses, and is a feature of such cases. With the

[1] Occidental Medical Times, San Francisco, November, 1896.

[2] Principles and Practice of Medicine, 1886, pp. 526 and 551. In one case the respiration ceased thirty-five minutes before death, in another of multiple cerebral abscess in the posterior and middle lobes the breathing stopped ten minutes before death occurred.

Digitized by Google

cessation of respiratory function we might expect a marked reduction of temperature to an even greater degree than occurred in these cases. In my case there had been a free employment of phenacetin, which might have still more reduced the temperature. The occurrence of suspended respiration for several hours in the highest mammalian organism, together with that of continued circulation of the blood for long periods, is very remarkable. Respiration may be carried on in animals which have been depleted of their blood and have had water introduced in place of it. But, in fact, with respiratory cessation death has practically already begun, and the respiratory centre, unless relieved of undue pressure, ceases to act. Although in such close proximity to the cardiac centre, the former is clearly much the more sensitive of the two, and lesions involving both tell primarily and with most force upon it. We may take it that the respiratory centre is the first to give out, and that it is the most vulnerable of all the great organic nerve-centres, the first to resent undue intracranial pressure. The clinical lessons of cases such as I have described are the following: 1. That efforts be made promptly to relieve intracranial pressure by trephining and probing. 2. To maintain artificial respiration diligently as long as necessary; that is, until the respiratory centre can resume its function independently. 3. To regard a lowered temperature as no contra-indication of purulent foci or hæmorrhagic foci in the brain. The fact of depressed or normal temperature is as significant in these cases as is the same occurrence in many examples of purulent peritonitis. I desire to express my thanks to my hospital colleagues for kindly allowing me to make use of their cases for this communication."

Dr. J. LINDSAY STEVEN (Glasgow) read a paper on a Case of Hypertrophic Pulmonary Osteo-arthropathy of Marie, without Pulmonary Disease, in the Section of Medicine, on Wednesday, Aug. 25th. Water-colour drawings, photographs, and skiagrams in illustration of the salient features were exhibited. The patient was a man, aged forty-eight years. He had been ill for about nine months. He first noticed enlargement of the hands and feet, but had not been disabled until eight or nine weeks before admission, when pain in the ankles and inability to close the hands obliged him to give up work. The deformity of the hands was typically that described by Marie as characteristic of pulmonary osteo-arthropathy. Skiagrams showed that this was due to subperiosteal new formation of bone. There was a corresponding deformity of the feet. There was no deformity of the face, trunk, or spine, and there was no retro-sternal dulness. There was, however, some deficiency of the temporal half of the visual field, and the daily average quantity of urine was decidedly excessive. There was absolutely no sign of disease in the chest, either in the heart or lungs. The relationships of the disease to acromegaly, osteitis deformans of Paget, and Marie's osteo-arthropathy were fully considered. On the whole Dr. Lindsay Steven considered that the symptoms conformed most to the last of these three affections. It was remarkable, however, that there was no pulmonary disease to account, on Marie's hypothesis, for the causation of the bone affection.

SECTION VI.

DISEASES OF CHILDREN.

The proceedings of this section on the first day were of great interest, a paper upon Chronic Nephritis and Albuminuria in Childhood from Professor HUEBNER evoking discussion from Professor COMBY, Professor VON STARCK (Kiel), Professor LEVESTRE, Professor VARGAS, Dr. LANGE, Dr. KATZ, and Dr. HOCHSINGER — Professor VON RANKE read a paper giving the results of cases of "ponction en ceinture" in Hydrocephalus, which was discussed by Professor MONTI, Professor FALKENHEIM, Professor RACZEWSKY, Professor CONCETTI, Professor BOKAY (Budapest), Dr. ALEXANDROFF, Dr. MARTIN GIL (Malaga), Dr. MEINERT (Dresden), Dr. LANGE, Dr. MENDEZ, Dr. TOLOSI-LATOUR, and others. — Papers were also read upon Empyema in Children by Dr. CAMILLO HAJECH (Milan); the Normal Properties of Blood and their Different Modifications in the Sick of Various Ages, by Professor BAGINSKY (Berlin); Icterus Neonatorum, by Dr. WERMEL (Moscow); and Organo-therapy with Kidney Substance in Renal Disease, by Professor CONCETTI (Rome).

In the same section on Saturday, Aug. 21st, Professor MONTI read a paper upon the Results of Laparotomy in Tuberculous Peritonitis; Dr. VIOLI (Constantinople) dealt with Whooping-cough complicated with Influenza; Dr. JALABERT (Barcelona) with Serum Therapeutics in Various Diseases of Childhood; Dr. ROMNICIANO (Bucharest) with Hereditary Syphilis; and Professor MONTI presented Some Statistics of the Results of Serum Therapeutics in Diphtheria and other Diseases.—In the afternoon there was a discussion upon Intubation of the Larynx, in which, amongst others, Professor BOKAY (Budapest), Dr. BOULAY, and Dr. TSAKWIS took part.

On Sunday, Aug. 22nd, combined *séances* were held between this section and those of Hygiene, Laryngology, and General Therapeutics.—Discussions took place upon the Influence of Mental Work upon the Health and Physical Development of Children and upon Physical Education, in which, amongst others, Dr. WIRENIUS (St. Petersburg), Dr. MENELLA (Rome), Madame WINOGRADOWA-LUKIERSKAJA (Moscow), Professor BARANOWSKY (Lemberg), and Professor PALMBERG (Helsingfors) took part.—Papers upon Infant Mortality, Vaccination, &c., were also read.

On Monday, Aug. 23rd, the Sections of Therapeutics, Diseases of Children, and Laryngology held an important combined *séance*, when a large number of statistics were presented by various members of the Results of the Use of Anti diphtheritic Serum, which were uniformly good and encouraging.—Dr. FIBIGER (Copenhagen) submitted the figures relative to a series of cases treated in the Blegdam Hospital, and constituting a year's practice in the hospital, concerning which he made the following claim: "*On a ainsi fourni une épreuve indiscutable de l'efficacité du serum anti-diphthérique, comme les résultats le prouvent*"—and Dr. VIOLI (Constantinople) spoke with hardly less emphasis.—Professor ROMNICIANO (Bucharest) read a useful paper upon the Possible Accidents Attendant upon Sero-therapy in Diphtheria, the net result of his conclusions being to recommend that no injection should be made until a bacteriological examination of the throat has confirmed the diagnosis of diphtheria.—Dr. PUJADOR Y FAUVA (Barcelona) recommended a new treatment of Scarlet Fever by Hypodermic Injections of Turpentine, which in his opinion not only cut short the disease, but was a prophylactic of scarlatinal nephritis.

On Tuesday, Aug 24th, a discussion took place upon the Artificial Feeding of Infants, in which, among others, Professor ESCHERICH, Professor JOHANNESSEN (Christiania), Dr. COTTON (Chicago), and Dr. FLACHS (Dresden) took part.—The Russian System of Foundling Hospitals and its Results were described and discussed by Dr. VAN PUTEREN (St. Petersburg), Dr. MASSINI (Genoa), and Dr. ARGUMOSA (Madrid).

On Wednesday, Aug. 25th, a short sitting was occupied with papers upon Vaccination and Disorders of the Gastro-intestinal Mucous Membrane by Dr. VIOLI (Constantinople) and Professor FEDE (Naples).

SECTION VII.

MENTAL DISEASES.

This section was opened with a few words of welcome by Dr. KOJEVNIKOF, one of the Presidents, the members present afterwards at his request announcing in turn each his name, which was received with plaudits varying with its being more or less generally known. Amongst those present were: Dr. Mierzeiewsky (St. Petersburg), Dr. Konstantinowsky (Moscow), Dr. Krafft-Ebing (Vienna), Dr. Erb (Heidelberg), Dr. Lombroso (Turin), Dr. Pitres and Dr. Régis (Bordeaux), Dr. Bernheim (Nancy), and Dr. Bérillon (Paris); and as delegates from Great Britain, Dr. Yellowlees, Dr. Finegan, Dr. Fletcher Beach, Dr. Cassidy, Dr. Macdonald, Dr. Shuttleworth, and Dr. Sutherland. The first day's papers were exclusively in French and German, authors of English communications promised not being present when called on.

The first subject discussed was that of Obsessions and Fixed Ideas. Dr. PITRES and Dr. RÉGIS presented a lengthy "Report," and other papers were read by Dr. BOUCHER (Rouen), Dr. MARIE and Dr. CH. VALLON, Dr. OTTO DORNBLÜTH, and Dr. KONSTANTINOWSKY. — Dr. RÉGIS distinguished between (1) panophobic and monophobic states, and (2) obsession properly so called, dividing the latter into ideative, impulsory, and hallucinative obsessions. He discussed the etiology, course, prognosis, and termination of obsessions, and distinguished them, on the one hand, from fixed ideas, and, on the other hand, from psychoses, such as melancholia, and from neuroses, such as hysteria

Digitized by Google

and neurasthenia. In conclusion, he discussed the moral and medical means of treatment of such cases, stating that they were apt to prove refractory to hypnotic suggestion, but that gentle, soothing measures, with baths, electrotherapy, and physical exercises were beneficial.

Dr. BOUCHER read a paper on Hereditary Erythrophobia (fear of the colour red), and Dr. MARIE discussed other forms of obsessions, whilst Dr. KONSTANTINOWSKY gave instances of psychic phenomena with the character of irresistibility, which he contended did not properly fall under the category of obsessions as set forth by Westphal. The pathogeny of general paralysis of the insane and its delimitation from other forms of disease presenting similar symptoms (such as syphilitic disease, tabes, and, in the early stages, neurasthenia) was the next subject discussed.—Professor BINSWANGER (Jena) treated the subject from the pathological standpoint, and Dr. MURATOW (Moscow) and Dr. GREIDENBERG (Symferopol) from that of clinical experience, the latter contending that general paralysis is becoming an "aristocratic" disease amongst men and a "democratic" disease amongst women.

Professor HOMÉN (Helsingfors) read an interesting account of three cases of Juvenile Progressive Dementia in three children of the same parents, probably from inherited syphilis.

On the third day of Congress there was a combined sitting of the sections of Neurology and Histology to consider the subject of the Pathology of the Nerve Cell. Reports were presented by Professor VAN GEHUCHTEN (Louvain) Professor OROSIANERIKOW (St. Petersburg), Professor APATHY (Hungary), and Professor MARINESCO (Bucharest). Professor VAN GEHUCHTEN agreed with the observations of Cajal as regards the reticulated structure of the achromatic substance; and Professor MARINESCO concludes that the nerve cell consists of three essential elements: (1) a chromatic element, highly colourable by aniline, which he designates *élément chromatophile*; (2) an achromatic figured element; and (3) an amorphic achromatic element, the last giving substance, the two first-named giving definite form, to the cell.

On Sunday, Aug. 22nd, Professor LOMBROSO presided, and the theme was Hypnotism and Suggestion in their Relation to Legal Medicine and Mental Maladies. Professor BERNHEIM (Nancy) had prepared a report on this subject, the conclusions of which were as follows: 1. "Suggestibility" is a physiological property of the human brain; it is the tendency of the brain to realise every idea accepted by it. 2. Every accepted idea is a suggestion. Hypnotism is not a special state; it is putting into action the property of suggestibility, with or without sleep. 3. Suggestion can be made to call forth in certain persons criminal acts, whether by instinctive impulsion or by hallucination or by perversion of the moral sense. 4. Suggestion cannot destroy a robust moral sense, or create it when it is absent; it can but develop existing germs of good and bad. ..... 7. Congenital feebleness of the moral sense and proneness to suggestibility facilitate suggestions to crime. ..... 10. Absolutely free choice of action does not exist. It is often impossible to apportion the degree of responsibility in a given case. Society has but the right of self-defence and of social prophylaxis. 11. Education ought to intervene to neutralise germs of evil and oppose to natural instinctive impulses the counterpoise of restraining suggestions.

Dr. TOKARSKY (Moscow) afterwards read a paper on the Application of Hypnotic Suggestion in the Treatment of Mental Maladies, laying stress upon its beneficial effect in the period of convalescence; and Dr. BÉRILLON (Paris) recommended hypnotic suggestion in the education of children hereditarily degenerate.

The sitting of Aug. 23rd was devoted to the discussion of Tabes Dorsalis, its Pathogeny and Treatment. Professor OBERSTEINER (Vienna) presented a report on the subject, discussing its etiology and its pathological anatomy. The same subject was treated specially in relation with its cerebral localisations by Professor PIERRET (Lyon) and Professor ERB and Professor BENEDIKT also stated their views at considerable length. Dr. BROWN (Chicago) contributed observations on the treatment of the disease, founded upon its pathology as a sclerosis terminating in hypertrophy of the connective tissue and a destruction of the sensory neurons of the cord. Recognising the syphilitic origin of some 90 per cent. of the cases, he approved of anti-syphilitic treatment in the very early stage of the affection (pre-ataxic), but later preferred chloride of gold and sodium as an alterative. He placed reliance also on phosphide of zinc, alternated with arsenic. Rest, an equable climate, electricity, cold or tepid baths, and in recurring cases suspension were specially indicated. The paper which attracted most attention with reference to the treatment of tabes was that read by Dr. GRASSET (Montpelier). In eloquent language he discussed the nosology of tabes, pointing out its anatomical and clinical features, and defining it as a "syndromic" manifestation of multiple sclerosis, the origin of which was frequently of complex character. He admitted that syphilis was a preponderant cause, but the neuropathic constitution was also an element in the disease. Though cure was rare, it was possible in the clinical sense though certain anatomical lesions might remain. Treatment must be directed (1) to the causal elements; (2) to the lesions; and (3) to the symptoms, anti-syphilitic and anti-arthritic remedies being useful for the first, ergot and the iodides to the second, and sedatives for the lightning pains. For the ataxia Frenkel's methods were of service, and in certain cases hypnotism, hydro-therapeutics, and electric treatment were called for.—Subsequently Dr. FRENKEL (Heiden) read a paper on the Treatment of Tabes and gave a demonstration of apparatus used by him; and Dr. G. E. SHUTTLEWORTH made an interesting communication upon Hereditary Neurosis in Children, of which the following is an abstract. Dr. Shuttleworth defined neurosis as an abnormal condition of the nervous system tending to disorder of function, not obviously connected with structural change, but often associated with trophic defect. He proceeded to show how hereditary neurosis implied abnormal irritability of nervous tissue, and consequent instability of function manifesting itself by sensory, motor, and psychic disturbances. In so-called nervous families were found mentally and morally defective children—children liable to eclampsic, convulsive, and choreic affections, and children who suffered from every form of "nerve-storm." Neurotic inheritance varied in form of manifestation in different generations and in members of the same generation; and this fact was illustrated by typical genealogical tables. The history of a degenerating family was passed in review in its downward course towards extinction. Statistics were given as to the hereditary influence of mental and nervous disease, of strumous and syphilitic taints, of alcoholism, of consanguinity, of senility, &c., in the parentage in determining neuroses in the offspring. The views of Richarz and others as to pre-potentiality of one or other parent in the transmission of neurosis were considered, and the variety of form of inherited nervous disease in children was discussed. From the sociological standpoint the necessity of educating public opinion as to the harmfulness of the intermarriage of neurotic persons was insisted on; and the paper closed with some remarks upon the precautions called for in the up-bringing and education of children of neurotic inheritance.

On Tuesday, Aug. 25th, at the morning sitting, Professor JOLLY (Berlin) read a paper on the Psychical Accompaniments (Störungen) of Polyneuritis, and this was followed by a paper by Dr. ALEXANDER ROBERTSON (Glasgow), on Some New Methods of Treatment in Diseases of the Central Nervous System. In the first portion he referred to the application of heat and cold at graduated temperatures to the head and spine as a means of stimulating the brain and spinal cord to more active metabolic processes. Cases in which such treatment had proved beneficial (e.g., of stuporose insanity and catalepsy with stupor) were cited, and it was stated also to be useful in inflammatory and degenerative diseases of the spinal cord. The apparatus used was shown. Subsequently the mode of percussion of the skull useful in the diagnosis of tumour or other gross lesion of the surface of the brain was demonstrated. The subjects of psychic impression, the use of prolonged cold douche to the head, and electrisation of the medulla oblongata were also dealt with by Dr. ROBERTSON.

A communication by Professor MACEWEN (Glasgow) on Brain Surgery was promised for the combined sitting of the Neurology and Surgery Sections on the afternoon of the 24th, and a paper by Dr. J. F. SUTHERLAND (Deputy Commissioner in Lunacy for Scotland) on the Legal Bearings of the Transitory Mania of Alcoholic Drunkenness was read on the 25th.

SECTION VIII.

DERMATOLOGY AND SYPHILOGRAPHY.

In this section among other important papers may be mentioned one upon Acanthosis Nigricans by Professor

Digitized by Google

JANOWSKY (Prague), which led to a discussion between the author and Dr. HEUSS (Zürich), Dr. COUILLAUD (Paris), and Professor PETRINI (Bucharest); and one upon the Etiology of Area Celsi by Dr. H. RADCLIFFE CROCKER (London).

The section was opened on Friday, the 20th, under the presidency of Professor POSPÉLOW, who in his introductory address gave a historical sketch of the Rise and Development of Dermatology in Moscow and its culmination in the magnificent new clinique in which the *séances* of this section were held. The clinique was opened to patients on Sept. 1st, and will be the finest clinique devoted to dermatology in the world. It contains sixty beds, a complete system of baths, laboratories, &c. The lecture theatre, where this section met, was large and well lighted, and the walls were lined with glass cases containing models and drawings of diseases of the skin. There were about 200 members present. Dr. RADCLIFFE CROCKER was the only English representative of dermatology, and was one of the Presidents for the day. The first speaker was Professor TARNOWSKY, who read a paper on Syphilis as it Occurs in Russia, where it is very prevalent in some districts, varying from 20 per 1000 inhabitants to 25 per 1000 in Tambow and Saratov.—Professor GAY followed on the same subject, and then Professor HALLOPEAU and Professor GAUCHER (Paris) opened a discussion on Toxins as Pathogenic Factors in Diseases of the Skin, and adduced strong arguments to show that toxins would play an important part in etiological researches in the near future. Dr. LASSAR, Dr. UNNA, and Dr. BARTHÉLÉMY joined in the discussion.

On Saturday, Aug. 21st, Professor KAPOSI (Vienna), Professor SCHWIMMER (Budapest), and Dr. SACH (Heidelberg) opened a discussion on Tuberculosis of the Skin, taking respectively Miliary, Primitive, and Verrucose Tuberculosis of the Skin.

On Sunday, Aug. 22nd, the Methods of Treatment of Syphilis by injection of soluble and insoluble salts of mercury and by mercurialised serum engaged the attention of the section throughout the *séance*, Dr. WOLFF (Strasburg), Dr. JULLIEN (Paris), Dr. GAUCHER (Paris), Dr. SOFFIANTINI (Milan), Dr. TARNOWSKY and Dr. JAKOWLEFF (St. Petersburg) being the chief speakers.

On Monday, Aug. 23rd, the Time when the Treatment of Syphilis should be Commenced and How Long it Should be Continued produced an animated discussion by Dr. SCHWIMMER, Dr. WATRASCHEWSKI (Warsaw), Dr. JULLIEN, Dr. LASSAR, Dr. VON ZEISSL, junior, Dr. COLOMBINI, and Dr. ROSENTHAL.—Dr. DE AMICIS then read a paper illustrated by numerous drawings on the Varieties of Sarcoma of the Skin.—This was followed by a discussion on the Pathogeny of Alopecia Areata, introduced by Dr. RADCLIFFE CROCKER, of which the following is an abstract. The conclusions are based on 432 hospital cases and 200 consecutive cases in private practice. The hospital cases show a frequency of 2·5 per cent.; 232 were males and 200 were females. No case occurred under two years or over sixty years (in private practice there were three cases between sixty and sixty-five years). Between the ages of five to fifteen years there were 180 cases, from fifteen to twenty-five years 90 cases, from twenty-five to thirty-five years 89 cases, from thirty-five to forty-five years 49 cases, and from forty-five to fifty-five years 16 cases. Thus between the ages of five and thirty-five years there were no less than 359 cases out of the whole 432, while there were as many cases between five and fifteen years as there were between fifteen and thirty-five years, clearly showing that the disease largely predominates in childhood. Dr. Crocker considers that the diseases known as alopecia areata are divisible into two great classes—(1) alopecia neurotica; and (2) alopecia parasitica. Each class may be subdivided. Class I., although probably not representing 10 per cent. of the whole, may be divided into—Type I., alopecia universalis; Type II., alopecia localis *seu* neuritica; and Type III., alopecia circumscripta of Neumann placed provisionally in this class. Class II., to which alopecia areata should be restricted, is probably entirely parasitic and constitutes 90 per cent. of all the cases. There are two types at present recognisable: Type I., cases allied to, or connected with, tinea tonsurans; and Type II., cases connected with seborrhœa capitis. While Dr. Crocker believes that Type I. comprehends the great majority of cases he cannot state what is the proportion between the two types. Moreover, it is probable that just as there are several varieties of parasite which produce the condition we call tinea tonsurans, so there may be more than one kind of microbe capable of producing smooth bald patches such as we comprehend under alopecia areata. Thus the pea-sized smooth patches so often recorded in local outbreaks might well be due to a special form of microbe. Again, there might possibly be some differentiation between the band form and the patch form, though Dr. Crocker hitherto had been unable to form the conclusion that they were pathologically distinct. He brought forward evidence to show that the disease is to a limited extent contagious for adults as well as children; that there was reason to believe that it might be spread by various means, such as shaving, hair cutting, especially by the *tondeuse*, theatrical wigs, dirty cushions, as in railway carriages, &c., as well as directly from one person to another; that persons in close contact with ringworm sometimes developed alopecia areata; that ringworm itself might develop into alopecia areata; and that in those countries where tinea tonsurans was most common alopecia areata was also most common. With regard to seborrhœa and alopecia areata he described certain peculiarities in many of the cases in which bald patches were associated with extreme seborrhœa, but did not think that Sabouraud's conclusions, that the seborrhœic microbe was the cause of all alopecia areata, were conclusively proved or that it was consonant with all the clinical facts. Dr. Crocker asked the meeting to confine the discussion to Class II, as there was a general agreement as to the neurotic origin of Class I., and the only point left was as to whether it should be included under alopecia areata at all. With regard to Class II., he asked the meeting to state their views as to what proportion of cases the two classes represent; how far they agreed with the view that Class II. was parasitic, and what was the relation of alopecia areata to tinea tonsurans on the one hand or seborrhœa on the other, or was it due to some microbe unconnected with either? If the meeting admitted that Class II. was due to a parasite and therefore contagious, even though only in a very slight degree, should children affected with it be kept from school and segregated from other children? Dr. Crocker was followed by Dr. LASSAR (Berlin), Dr. MANASSÉÏN (St. Petersburg), and Dr. CIARROCCHI (Rome).—Dr. PETERSEN gave an interesting communication on Initial Forms of Leprosy, adducing two cases where the interior of the nose was first affected, possibly by inoculation of bacilli by the finger.

On Tuesday, Aug. 24th, the *séance* was held at the old clinique of Professor Pospélow, which contains 400 beds, almost all containing cases of syphilis. Three cases of leprosy were shown and a few cases of interest were exhibited on the previous days, but as a whole the number of clinical cases shown was very small.

The rest of the session was devoted to the reading of papers by Dr. CAMPANA, Dr. ROSENTHAL, Dr. UNNA, Dr. LASSAR, and others. The last two days, judging by the programme, would be occupied chiefly by subjects connected with gonorrhœa and syphilis. On the whole, except as regards the paucity of clinical material, the Section of Dermatology was very successful, well-organised, and well-attended.

SECTION IX.

SURGERY.

This section, like the Section of Medicine, suffered much by the multiplication of special sections, so that many papers which we are wont to regard as on purely surgical subjects were read in sections dealing with Diseases of Children, with Ophthalmology, Odontology, and Otology, &c. Among interesting papers may be mentioned one by Professor VON BERGMANN (Berlin), upon the Operative Treatment of Jacksonian Epilepsy; one by Professor CZERNY upon the Various Methods of Treatment of Strictures of the Œsophagus and Rectum; and one by Professor OLLIER (Lyons) upon the Syphilitic and Gonorrhœal Affections of Joints.—Dr. J. LUCAS-CHAMPIONNIÈRE also made an interesting communication upon the Treatment of Certain Forms of Fracture, where the fractured ends are very mobile. He lays no stress upon the maintenance of complete immobility, but employs massage from the beginning.

SECTION X.

MILITARY MEDICINE.

Such very varying subjects as Ambulance Procedure on the Field of Battle, the Provision of a Good Water-supply

Digitized by Google

for a Marching Army, and the Best System of Education for an Army Medical Service, provided topics for discussion in this section.

SECTION XI.

OPHTHALMOLOGY.

Among the papers in this section which led to discussion or attracted notice may be mentioned one by Professor ANGELUCCI (Palermo) and one by Professor KUHNT (Königsberg) on the Treatment of Trachoma; one by Dr. KNAPP (New York) on the Nature and Mechanical Treatment of Granular Conjunctivitis; one by Professor PAGENSTECHER (Wiesbaden) on the Treatment of Asthenopia; and one by Professor L. BELLARMINOV (St. Petersburg) upon the organised work of the Société Marie in Russia for the Alleviation of the Blind.

SECTION XII. (A AND B).

DISEASES OF THE EAR, THROAT, AND NOSE.

The most important work done in this section has already been referred to in the Section of Diseases of Children. The testimony of the special workers to the efficacy of the antitoxin treatment of diphtheria was especially valuable.

SECTION XIII. (A AND B).

OBSTETRICS AND GYNÆCOLOGY.

Under the heading of Obstetrics three subjects led to discussion among the members who attended the work of this section, viz.: Symphyseotomy, upon which operative measure Professor VARNIER (Paris), Professor ZWEIFEL (Leipzig), and Professor BOSSI (Genoa) addressed the meeting; Sero-therapy Applied to Puerperal Septicæmia, upon which Professor BAR (Paris), Dr. WEINSTEIN (Odessa), and Dr. WALLICH (Paris) spoke; and the External Examination of the Uterus, when the meeting heard the views of Professor LEOPOLD (Dresden), Professor HENNIG (Leipzig), and Professor PINARD (Paris).

Under the heading of Gynæcology the chief theme of discussion was Colpotomy in Inflammation of the Adnexa and in Neoplasms of the Uterus, when Professor CANDELA (Valence), Professor DOYEN (Rheims), Professor DÜHRSSEN (Berlin) and Professor MARTIN (Berlin) spoke. Several papers were also announced on the Electrical Treatment of Fibroids and of the results of Extra-Uterine Conception. Among these may be mentioned a paper by Dr. T. P. NEDOBODOFF (Moscow) entitled "Le Traitement et Guérison Complète par l'Électricité de la Grossesse Extra-utérine et de ses Suites," in which the author came to the following conclusions: (1) the first stages of extra-uterine pregnancy can be successfully treated by electricity; (2) until the middle of the fourth month electrical methods can probably be employed with advantage; (3) where degeneration into hæmatosalpinx has taken place electrical therapeutics are the only ones practicable; and (4) even in slowly forming peri-uterine hæmatoceles electricity may be tried with success.

SECTION XIV.

HYGIENE, PUBLIC MEDICINE, SANITARY STATISTICS, AND EPIDEMIOLOGY.

This section was throughout largely attended, and many of the papers set down to be read in it would have been naturally read in the Section of Medicine, which certainly suffered by these elaborate sub-divisions. On the first day (Aug. 20th) there were interesting papers read, among others, by Dr. BURGERSTEIN (Vienna), upon the Propagation of Sanitary Knowledge among the Populace; and by Professor VICTOR C VAUGHAN (Michigan, U.S.A.) on the Bacteriological Examination of Drinking Water. Professor VAUGHAN said that he had been engaged for the past nine years in making bacteriological examinations of water suspected of causing typhoid fever. The examination had consisted of the ordinary plate tests and counting the number of germs per cubic centimetre, but in addition to this animals had been inoculated with mixed and pure cultures of the germs obtained from each of the waters examined. The pathogenic germs which were found could be divided into two classes, first, those of the colon group, and, second, those resembling the typhoid bacillus. Waters containing germs belonging to the colon group had not been condemned by him, while those containing germs resembling the typhoid bacillus had been condemned. The fact that in every instance the epidemic of typhoid fever had ceased on the discontinuance of the condemned water indicated that such analyses were of practical value.

On the following day, Aug. 21st, an interesting paper was read by Mme. M. I. POKROVSKAÏA, (St. Petersburg) upon Workmen's Dwellings Abroad, in which she came to the following conclusions:—(1) That good workmen's dwellings are always popular; (2) that if worked upon economical lines they can be made a paying form of philanthropy; and (3) that the necessary rules and sanitary organisation conduce much to the sanitary well-being of the lower classes.

Professor EDWARD NOCARD (Alfort) read a paper upon Serum Therapeutics in Tetanus. He considered it under the headings of (*a*) its use as a curative agent and (*b*) as a prophylactic. He came to the following conclusions under the above two headings:—(*a*): 1. When tetanus has once declared itself the antitoxic serum has no action. It is powerless to arrest the fatal result of the malady, and this whatever be its strength or the amount of the dose injected. Those alone are cured who would have got well in any case. 2. The serum treatment is, however, useful even in declared tetanus, for even if the number of cures is not increased, yet those who do recover do so more quickly, the tetanic crises are less numerous and less violent, and the period of convalescence is much shorter. (*b*): 1. The antitoxic serum, even in a weak dose, if injected at the moment of reception of the suspicious injury, or even some time after its reception will prevent the onset of tetanus. 2. The dose injected must be both larger and stronger according to the length of time intervening between the reception of the wound and the employment of the serum. Intravenous injections are better than hypodermic; the attack of tetanus is not always warded off, but, as a rule, if it does appear, it is of a mild quality and the animal soon gets well even when it has received a dose of toxin invariably fatal to a control animal.

The members of this section were escorted one afternoon to see the abattoirs of the city of MOSCOW, which are situated some miles outside the city. The abattoirs are large, well-arranged, and well managed, and their being situated thus far from the city obviates one source of sanitary nuisance.

SECTION XV.

LEGAL MEDICINE.

Among the topics set down for discussion in this section may be mentioned the Creation of a Special Profession to be known as Médecins-Légistes, a suggestion brought forward by Professor PATSNNKO (Kharkof); the Application of Bacteriological Research to Medical Jurisprudence, a paper on which subject was read by Professor LACASSAGNE (Lyons); and the Adequate Penalty for Sexual Crime, which subject was introduced by Professor KRATTER (Graz).

In this section an interesting paper was read by Dr. J. F. SUTHERLAND, Deputy Commissioner in Lunacy for Scotland, on the Temporary Mania of Intoxication and the Anomalous Attitude of Civil and Criminal Law. The following is a brief *résumé* of the paper. The writer, in respectfully submitting to the medical jurists and specialists of every civilised nation assembled in the ancient capital of Russia his views on the attitude of the criminal law with respect to crimes committed by persons in a state of intoxication, contends that the criminal code which regards the authors of crimes such as murder, culpable homicide, &c., as fully responsible to the law, and thus places them on the same footing as criminals actuated by *malice prepense*, is not only not in harmony with the views expressed by modern schools of jurisprudence and ethics in the closing years of the nineteenth century, but is positively cruel and unjust, and warranting the suggestion, if not the appellation, of such a code being a draconian one. The position of Great Britain is not an enviable one. In regard to her criminal code, and her attitude towards drunkenness and habitual drunkenness, her place is not in the European concert. But her voluntary exclusion, it is to be hoped, is only a matter of time. Drunkenness is a perfect picture of insanity—none more so in the whole range of lunacy. The anomalous, not to say illogical and unjust, attitude of the criminal law is heightened by a consideration of the attitude of the civil law, which to all intents and purposes shields the drunkard from the consequences of civil acts, testamentary dispositions, and contracts made in a state of intoxication. As a justification of their position it has been urged by a school of jurists, who neither admit the insanity plea nor

Digitized by Google

take cognisance of important questions such as free will, biology, sociology, &c., that the scaffold, the guillotine, and electrocution are deterrents to the drunkard. There could be no greater delusion. They may be, and no doubt are, to the deliberate murderer, but they come not within the vision, mental or physical, of the man intoxicated. When he begins imbibing he does not mean crime, least of all murder. When he has drunk he is past the reflective stage, and with will power paralysed acts like a madman. In this connexion it is worthy of observation that most drunkards are potential murderers. It is the merest accident that the assaults they commit do not terminate fatally, and that as a consequence capital punishments are not multiplied a thousandfold. It is not their fault; the violence is not measured. Everyone recognises alcohol as a brain poison, producing certain well defined mental derangements—in short, insanity. But drunkenness, says the law, is a form of insanity which must not, like the other insanities induced by alcohol or by vice, exculpate or modify guilt. Judged by criterions of responsibility—above all, that laid down by the bench of judges in 1843—such a view is illogical and untenable. There are, apart from the views of the law and its criterion of responsibility, other considerations more or less significant which should make jurisprudence — ofttimes hampered by a fetich regard for precedents—more merciful towards such offenders. In considering the fate and punishment of drunkards who have committed crimes regard should be had by the judiciary and by juries to—(1) the attitude of the civil law, which protects the drunkard from the consequences of his acts, practically recognising his condition as being one of *non compos mentis*; (2) the attitude of the law towards drunkenness *per se* and habitual drunkenness (as a matter of fact, both are winked at by the laws of Great Britain until a crime is committed); with such a state of matters as this there is no excuse for the severity of the criminal code; (3) the nature of the toxic beverage—made highly toxic by the presence of adulterations and sold freely with the sanction of law; (4) climate, race, and temperament—the Teutonic being as a rule more prone to excesses than the Gallic, and the Gallic than the Slavonic; and (5) the fact that the defence of such criminals is left to youthful and inexperienced lawyers, who have no means provided to make the best case possible by the employment of eminent counsel and skilled witnesses, while the prosecution is conducted with the most powerful resources of the State.

THE MEETING OF THE BRITISH MEDICAL ASSOCIATION AT MONTREAL.

THE sixty-fifth annual meeting of the British Medical Association commenced upon Aug. 31st at Montreal. Upon Sept. 1st the McGill University conferred honorary degrees upon the following:—Lord Lister, Professor Richet, Sir Walter Foster, Sir William Turner, Dr. H. Barnes, Dr. Michael Foster, Dr. Gaskell, Mr. Christopher Heath, Dr. Alexander Macalister, Dr. Saundby, and Mr. Wheelhouse.

Owing to the pressure upon our columns, due to the International Medical Congress at Moscow, we are unable to find space this week for all the addresses, but that of the President and those of the Presidents of the Sections of Medicine and Surgery will be found in another column. Abstracts of the others, together with details of the proceedings, will be published in future issues.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the subjects indicated:—

Surgery.—L. L. Allen, St. Bartholomew's Hospital; P. S. Blaker, Calcutta; J. B. Cautley (Section I.), St. Bartholomew's Hospital; J. W. F. Rait, University College Hospital; L. Tong, Manchester; C. A. Trouncer, Cambridge and Guy's Hospital; and E. M. Vernon (Section II.), Royal Free Hospital.

Medicine.—E. L. Anderson, Liverpool; S. R. Bhagtani, King's College Hospital; E. C. Corfield, St. Bartholomew's Hospital; D. F. Maunsell, St. Thomas's Hospital; C. C. Poole, Guy's Hospital; G. Steel, Cambridge University; C. A. Trouncer, Cambridge and Guy's Hospital; E. M. Vernon (Section II.), Royal Free Hospital; S. K. Vines, Birmingham; and A. M. Weir, Royal Free Hospital.

Forensic Medicine.—H. A. Ahrens, King's College Hospital; E. L. Anderson, Liverpool; E. C. Corfield, St. Bartholomew's Hospital; D. F. Maunsell, St. Thomas's Hospital; C. C. Poole, Guy's Hospital; W. A. H. B. Smith, King's College Hospital; G. Steel, Cambridge University; C. A. Trouncer, Cambridge and Guy's Hospital; S. K. Vines, Birmingham; and J. H. Wilson, Middlesex Hospital.

Midwifery.—E. L. Anderson, Liverpool; S. R. Bhagtani, King's College Hospital; E. C. Corfield, St. Bartholomew's Hospital; D. F. Maunsell, St. Thomas's Hospital; C. C. Poole, Guy's Hospital; G. Steel, Cambridge University; C. A. Trouncer, Cambridge and Guy's Hospital; S. K. Vines, Birmingham; and A. M. Weir, Royal Free Hospital.

The diploma of the society was granted to the following candidates, entitling them to practise Medicine, Surgery, and Midwifery:—E. C. Corfield; J. W. F. Rait; G. Steel; C. A. Trouncer, E. M. Vernon, and S. K. Vines.

REGISTRATION OF PLUMBERS.—An examination of master and operative plumbers applying for registration under the National Registration of Plumbers was held on Aug. 28th by the Worshipful Company of Plumbers at the Borough Polytechnic Institute. Twenty-six candidates were present from various parts of London and the following provincial towns:—Lyme Regis, Maidstone, St. Peter's (Kent), Bishops Stortford, Southend-on-Sea, Eton, and Haywards Heath. The practical tests included lead bossing, pipe bending, and joint making. The examination questions included the subjects of roof covering, contamination of drinking water from faulty connexions, arrangement of bath, sink, and closet wastes, drainage of town houses, and disconnexion with sewers. The examiners were:—Mr. Charles Hudson, Chairman of the Board of Examiners, Mr. J. Knight, Master Plumber, Mr. G. Taylor, Foreman Plumber, Messrs. F. Randall and F. Barter, Representatives of the United Operative Plumbers' Associations of great Britain and Ireland, and Mr. C. T. Millis, Principal of the Educational Department, Borough Polytechnic Institute. Five candidates succeeded in passing the examination in practical workmanship.

THE QUARTERLY COURT OF THE MIDDLESEX HOSPITAL.—A meeting of the Quarterly Court of Governors of the Middlesex Hospital was held on Aug. 26th, and a summary of transactions of the weekly board of Governors was laid before the meeting. Among other things the board had the honour to report that His Royal Highness the Duke of Cambridge, K G, Vice-President, in accordance with the resolution of the Special General Court held in May last, presented the loyal address of the Governors and medical staff of the hospital to their most gracious patron the Queen on the auspicious occasion of the sixtieth anniversary of her beneficent reign, and the address was very graciously received by Her Majesty. The foundation-stone of the new wing for female cancer patients had been laid on July 15th by Her Royal Highness the Princess Christian of Schleswig-Holstein. The erection of a temporary building in the hospital garden has been sanctioned to enable the school authorities to carry on the work of the Anatomical and Chemical Departments while the proposed alterations and extensions to the medical school are in course of progress. The Council has announced that Baron Strathcona and Mount Royal of Glencoe, K.C.M.G., High Commissioner of Canada, and Chancellor of McGill University, Montreal, will address the students at the opening of the Winter Session on Oct. 4th next. Among the legacies received during the quarter the further munificent sum of £10,000 has been paid over by the executors of the late Mr. David Brandon, being on account of one-sixth of the residue of his estate bequeathed to the hospital, in addition to the specific bequest of £3000 already paid and reported to the last court. The donations list for the past quarter includes £1000 from "Cambridge" and £500 "Anonymous" (per Dr. Arthur Francis Voelcker), both to the Cancer Fund. The Convalescent Home at Clacton-on-Sea has been kept full, no less than 251 patients having been admitted during the quarter ending June 30th. With deep regret the board had to record the death of Dr. Henry Thompson, consulting physician to the hospital, who died on July 22nd. The board have approved with other hospitals a scheme for the formation of a Central Association of Representatives of London Hospitals with Medical Schools, the object of the association being to consider any matter in which the hospitals have a common interest and to promote joint action in regard thereto.

THE LONDON HOSPITAL.—The quarterly court of governors of the London Hospital was held on Sept. 1st. The secretary read the quarterly report, stating that the number of patients discharged cured was 1297, number relieved 1131; died 260; giving a total of 2688. The out-patients numbered 14,363. The chairman, in moving the adoption of the report, said that they had received from the Brandon legacy £10,000 during the present quarter, in addition to £3000 received from the same source before The Grocers' Company had continued their donation of £1000, and Mr. Page had given £1000. He was opposed to such an organisation as a central hospital board. The Prince of Wales's Fund had not as much effect as they had expected in the direction of a reduction of subscriptions, but nevertheless it had had some. The idea with which the fund was started was a grand one, but he was afraid that only a sixth of the necessary amount had been promised. Although their expenditure at the London Hospital was £60,000 per annum, and their assured income was only £20,000, he was confident they would carry on their work with the same efficiency as in the past. This motion was seconded by Mr. J. Hall and adopted.

CHURCH SANITARY ASSOCIATION.—We have just received the report of the annual meeting of the Church Sanitary Association, which was held at 1, Hamilton-terrace, London, on May 11th, under the presidency of Dr. Norman Kerr, in the unavoidable absence of the Bishop of Coventry. Founded six years ago with the view of promoting sanitary reform in every parish, this society has adopted the method of making use, as far as possible, of the parochial organisation of the church, and of endeavouring to induce preachers and teachers to enforce the obligation that rests upon all, to care "as well for the body as the soul." The Gospel appointed to be read in every church on the seventh Sunday after Trinity has been suggested as affording an opportunity of bringing the aims of the society to the notice of the public generally. During the past year sermons were preached, meetings were held, leaflets and pamphlets were distributed, and numerous communications were sent to the press; a memorial to the Government asking for proper inspection of meat before it was offered for sale was very largely signed, and during the Church Congress at Shrewsbury special efforts were made to have instruction respecting the health and temporal welfare of mankind reckoned as an integral part of the Church's work. The Archbishop of York is president of the association, the Duke of Westminster and Major E F. Coates are patrons, and the Rev. F. Lawrence, Westow Vicarage, York, is treasurer and secretary.

BOOKS, ETC., RECEIVED.

BALE, JOHN, SONS, AND DANIELSON, Great Titchfield-street, Oxford-street, London.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1897, which was completed with the issue of June 26th, was given in THE LANCET of July 3rd. It is intended, in future, to include the Index and Title-page for each past half-yearly volume in the first number of the succeeding volume, as in the present case, instead of in the last number of the volume itself, as heretofore.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1897 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

THE TAXING OF MEDICAL MEN IN AMERICA.

IT seems that in some of the States of the American Union medical men have to pay a tax for practising their profession. The *Virginia Medical Semi-Monthly* says that the State of Virginia has been charging for the past ten years or more $25.75 (£5) for the licence of a city medical man who has been in practice five or more years, and for the past two years, in addition to this, the Richmond City Council has imposed the city licence tax varying from $20 (£4) to $75 (£15), according to the income received, a medical man of average prominence having to pay from $40 to $60 (from £8 to £12) a year.

"SAVE US FROM OUR FRIENDS."

SOME indiscreet friend of Sir William MacCormac seems to have the use of the *Cambria Daily Leader*, and draws a melancholy picture of Harley-street without the President of the Royal College of Surgeons. "Sir William has been presented to the Czar, a distinction reserved for only a few of the Conference, which numbers 6000 members. The President of the Royal College, however, is a man who has attained his position by sheer merit, and remains the same plain hard-worker, whatever the courtly honours he receives." Then follows an account of the President's dog and its place in its master's consulting-room. Such accounts are presumably meant to entertain the readers of our Cambrian contemporary in this very dull season, and soothe the crowds of *malades imaginaires* who will have no deputy and sigh for the return of Sir William MacCormac and other distinguished consultants.

Mr. N. Hay Forbes.—We do not think that there is one. "Bellows' French Dictionary" (Trübner and Co.) contains a great many medical and scientific terms and would be found useful.

"KISSING THE BOOK."

THE *Maryland Medical Journal* states that a sanitary Bible bound in celluloid which can be washed has been introduced into some courts.

Medicus.—Experience shows that the rheumatic and bronchial patients who winter in Ilfracombe derive much benefit. The temperature is equable without the humidity found in South Devon. The air is moderately bracing and sheltered from the east. The chief feature about the climate is the rapidity with which the roads dry after rain, the subsoil being of a porous and friable shale, which readily admits of the rapid percolation of surface water.

INCOME-TAX OVERCHARGES.

To the Editors of THE LANCET.

SIRS,—The interest which has been aroused in regard to income-tax by the correspondence in the *Times* and the articles which have appeared in a large number of other metropolitan and provincial papers has resulted in calling attention to many grievances which taxpayers suffer, but there is one practice of the Inland Revenue authorities which we think is quite unjustifiable, and which seems to have been overlooked. The practice referred to is that of sending to traders and others at this period of the year a blue notice of charge, showing an assessment of profits at £160 and allowing the whole by way of abatement, no tax being demanded in respect of the business profits. Of course, where those who receive such notices have no income from any source other than their business no injustice is done; but in the case of such as have income from other sources from which tax has already been deducted the effect is to bar their right to claim repayment, unless the assessment of the business profits be appealed against, the full abatement having already been allowed. It is, therefore, of the utmost importance that those of your readers who are now receiving notices of charge for the year 1897-98 should, if the amount at which they are assessed is greater than the average of their profits for the three years ending April 5th, 1897 (or at such prior date as they usually make up their accounts), at once give notice of appeal in accordance with the instructions on the notice of charge. Moreover, if they find that the profits of the three years named show an average profit less than the amount upon which they paid tax for 1896-97, they should give notice of appeal in respect of that year also, and claim repayment of the amount overpaid. There is no time to lose in business appeals, as this class of claim for repayment should have been made before now; while a claim to set off a loss in farming or business against income from other sources must be lodged before Oct. 6th next. Many people are now entitled to make a claim on one ground or another for three years to April 5th last.

We are, Sirs, yours faithfully,

THE INCOME-TAX ADJUSTMENT AGENCY.

12 and 13, Poultry, London, E.C., Sept. 1st, 1897.

Mr. J. M. B. Atkinson (Shrewsbury).—No very extended account of trional has appeared. A case of urobilinuria following its use was reported in THE LANCET of March 27th, 1897. If our correspondent applies to the agency for Bayer's drugs (The Elberfeld Farbenfabriken Co., 19, St. Dunstan's-hill, E.C.) he will probably be supplied with literature on the subject.

AN UNSEEMLY ADVERTISEMENT.

A CORRESPONDENT has sent us the following cutting from the *Portsmouth Evening News* of Aug. 27th:—

NOTICE.—Dr. Raitt has removed from Outram-road to more central and convenient premises, 38, St. Andrew's-road (corner of Margate-road). From 2 till 3: Private patients and engagements only.

Dr. Raitt should know that if he wishes to intimate a change of address to his patients this is not the way to do it.

SHARKS IN THE ADRIATIC.

EVER since the opening of the Suez Canal, thirty years ago, by which the Indian Ocean has been connected with the Mediterranean, sharks have increased in the latter sea. They follow the P. and O. liners, whose course involves touching at Brindisi, Ancona, and finally Venice. Some years of excessive sultriness have witnessed these unwelcome visitors in great force, particularly off the Adriatic watering-places. One of these, Sinigaglia—the bright, clean town so frequented for midsummer sea-bathing, celebrated, moreover, as the birthplace of Pius IX.—has suffered disastrously from the scare caused by the capture of several formidable sharks quite close to the land. In fact, the development of the place as a seaside resort in the dog-days has been appreciably affected by the gruesome monsters in question. From Ancona comes the announcement that recently a male shark, 1 metre 20 cm. long, its open mouth 48 cm. in length, was caught, not without difficulty, by some fishermen, who previously to its capture thrust between its jaws a "voliga" (a thick piece of wood the length of a walking-stick), which it instantaneously reduced to matches. Now this shark had doubtless a female consort in attendance—they seldom travel alone, and when not in shoals are almost invariably in couples—the wanderings of which in search of the missing spouse must keep the whole seaboard in alarm. At Venice the famous bathing ground known as the Lido is at this season frequented by thousands of visitors, including many of our compatriots *en route* to or from Egypt, India, or the Antipodes, and it is not without reason that the Venetian and Emilian journals sound a note of warning as to the danger of deep-sea bathing with the aforesaid "widowed cruiser" patrolling their waters. If the "midsummer nightmare" caused by these voracious privateers continues the Adriatic municipalities will have to offer a prize for each one captured, as in India a reward is given for the killing of snakes.

Vigilo et Spero.—We should gladly insert our correspondent's letter if we thought its insertion would do either him or others good. But we doubt this. His case is, we think, if not unique, very rare, and could scarcely be made the ground of an argument. We sincerely trust that his remaining powers and energy will ere long find fit and congenial employment.

"A VEILED NOMENCLATURE."

To the Editors of THE LANCET.

SIRS,—I think it will be an advantage if the next edition of the British Pharmacopœia contains synonyms for the drugs in common use. Medical men are constantly having their prescriptions commented on by their patients because the names of the drugs prescribed are so palpable. At present I am treating a lady who insists on seeing every prescription and on knowing every ingredient used. She has quoted to me from memory what Sir Russell Reynolds gave her; and on seeing a "spray" on her table which I inquired about she informed me that it contained cocaine, glycerine, &c., and was prescribed by Mr. So-and-so. On my writing, a prescription containing ammonium bromide and chloroform water she at once commented on these drugs, and I felt how desirable a "veiled nomenclature," if I may use the expression, would be for such patients.

I am, Sirs, yours faithfully,

Sept. 1st, 1897. M.D.

Mr. Owen Williams (Glandovey).—The statements of the writer of the letter forwarded to us have been exposed and contradicted over and over again.

PULQUE AS AN ANTI-SCORBUTIC.

DR. C. E. IDE, of Buffalo, writing in the *Philadelphia Polyclinic*, recommends pulque, a Mexican drink made from the juice of the Agave Americana, as an efficient prophylactic and remedy for scurvy. The juice of this plant was first employed in the treatment of scurvy by Dr. Peres, of the United States Army, and was considered by him to be superior to all other anti-scorbutics. Pulque is, according to Dr. Lobato, of Mexico, an acid wine, unrectified, produced by fermentation in aguamiel, the juice of the maguey or Agave Americana. This liquor is a familiar drink among the Mexicans and varies according to the region from which the plants are obtained, the best being that which comes from points on the Mesa Central Railroad—namely, from the plains of Apam, Tlaxcala, and Puebla. The aguamiel (juice) is obtained by scraping the maguey. It is a yellowish-white liquor, slightly viscid, with an agreeably sweet taste, and an aromatic smell due to an essential oil. It ferments spontaneously after a few hours' exposure to the air at from 18° to 20° C., developing alcohol; if the fermentation be not checked, acetic acid and, later, lactic acid are formed; finally putrefactive changes occur. Pulque can be administered almost *ad libitum*; it is not easily preserved for a long time, except by the aid of antiseptics.

THE MENTAL AFFECTIONS OF CHILDREN.

WE have pleasure in publishing the following notice:—

"Twenty years have passed since my book on 'Idiocy and Imbecility' appeared. I now desire to bring out a comprehensive treatise exposing my more mature views, gathering up scattered papers, and giving the outcome of the latest scientific inquiry. If I were assured of Two Hundred Subscribers I could, without risk of pecuniary loss, bring out a work on 'The Mental Affections of Children—Idiocy, Imbecility, and Insanity.' The book would contain about 300 pages, octavo, with illustrations, price to subscribers 8s. on delivery.

"I hope that those who make a study of neurology, insanity, and psychology, or take a kindly interest in the training of imbeciles, will help by subscribing for copies, which may be done by filling up a form which will be supplied on application to me.

"WILLIAM W. IRELAND.

"Mavisbush House, Polton, Midlothian."

Mr. H. T. Hamilton.—There are various formulæ which our correspondent will find in books of receipts—e.g., Cooley's Handbook.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (8th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. 'Tabloid' Hypophosph. Co.

The portability and ease of administration of the 'Tabloid' give it distinct advantages over the Syrup. Two sizes are made, 1-1/2 gr. and 3 gr., representing respectively 1/2 and 1 dr. of a standard Compound Syrup of Hypophosphites, containing 1/64 gr. of hypophosphite of strychnine and about 3 gr. of the hypophosphites of calcium, potassium, manganese, iron, and quinine to each drachm. The danger of over dosage from precipitation of strychnine is entirely avoided.

1½ gr., in bottles of 25 and 100 .. 9d. and 1s. 6d.
3 gr., in bottles of 25 and 100 .. 10d. and 2s.

BURROUGHS, WELLCOME & CO.,
LONDON and SYDNEY.

'Tabloid' Easton Syrup.

This 'tabloid' is made in two sizes, equivalent respectively to 1/2 and 1 drachm of Easton Syrup. The 'tabloid' overcomes all objections to the syrup on the score of taste, and will keep indefinitely in all climates. During prolonged treatment it can be carried and taken regularly without inconvenience. Each 'tabloid' is perfectly soluble and contains an exact dosage of each ingredient.

1/2 dr., in bottles of 25 and 100 .. 9d. and 1s. 6d.
1 dr., in bottles of 25 and 100 .. 10d. and 2s.

BURROUGHS, WELLCOME & CO.,
LONDON and SYDNEY.

'Saxin'

(Trade Mark.)

Is a delicious sweetening agent, about 600 times sweeter than sugar, and has been aptly termed 'the sweetest thing on earth.' 'Saxin' is indicated in diabetes, gout, glycosuria, obesity, etc., because it undergoes no change in the system. A 1/4 gr. of 'Saxin' is equivalent to one lump of best loaf sugar. A small bottle containing 100 or 200 can be easily carried in the vest pocket.

Supplied at 7d. and 1s. 1d. per bottle.

BURROUGHS, WELLCOME & CO.,
LONDON and SYDNEY.

'Emol-Keleet'

A natural powder containing a large proportion of native silicates, employed as a diluent for such potent therapeutic agents as Loretin, Iodoform, Dermatol, Boric Acid, etc., and as a drying and dusting powder.

Its soft, silky texture, soothing influence, and other valuable qualities enhance its healing action. It has proved successful for drying weeping surfaces when all other powders have failed.

Supplied in tins at 9d. each.

BURROUGHS, WELLCOME & CO.
LONDON and SYDNEY.

Value of "MALTINE"

"'**Maltine**' contains from three to five times as much diastase as any other Extract of Malt in the market."—Prof. ATTFIELD.

"As to diastase-converting power, '**Maltine**' is superior to the best Extracts of Malt I have ever seen."—Prof. STUTZER, Bonn.

"Repeated experiments show that '**Maltine**' converts from 25 to 30 times its own weight of starch into sugar."—Prof. C. MÉHU, Paris.

In Diastase.

"'**Maltine**' exhibits in an eminent degree the starch dissolving power of diastase; in fact, a teaspoonful is capable of converting instantaneously a surprising amount of stiff starch paste into a thin limpid liquid."—THE LANCET.

Albuminoids.

"Extracts of Malt (i e, malted barley) are pretty widely known, but in '**Maltine**' we find the first example of a combination of the nutritious principles of these three cereals. The *greater value* of this combination is apparent, as wheat and oats are especially rich in muscle- and fat-producing elements; clinical experience enables us to recommend it as a nutritive agent in virtue of its albuminoid contents."—BRITISH MEDICAL JOURNAL.

"'**Maltine**' contains more flesh forming substance than any other Extract of Malt."
—Prof. DEPAIRE, Brussels.

Phosphates.

"Contains more bone-producing substance than any other extract of Malt."
—Prof. DEPAIRE, Brussels.

Carbo-Hydrates.

"**Maltine**" contains a large proportion of the digested carbohydrates, dextrine and maltose. The superior diastasic activity of "**Maltine**" converts into assimilable form and utilises for the organism a far larger amount of farinaceous food than is the case with other extracts of malt.

International Health Exhibition, London, awarded the only GOLD MEDAL for Malt Extracts to "MALTINE."

The delicate flavour and convenient consistence of "MALTINE" recommend it to patients who cannot take the dense unpalatable extracts.

POINTS ABOUT

"MALTINE" WITH COD LIVER OIL:—

IT IS THOROUGHLY PALATABLE.

The delicate flavour of "Maltine" admirably adapts it for a menstruum for cod liver oil, and "Maltine" with Cod Liver Oil is tolerated with ease by the most fastidious.

IT IS READILY ASSIMILABLE.

The oil in "Maltine" with Cod Liver Oil is most minutely broken up, the division being far finer than that of the fat in milk. The combination being effected by mechanical means, is not disintegrated by acid, as is the case with emulsions. "Maltine" with Cod Liver Oil has been proved by clinical experience to be the most easily digested of all cod liver oil preparations.

IT IS HIGHLY NUTRITIVE.

In "Maltine" we have a powerful agent for the conversion of farinaceous food into soluble form, also a food rich in carbo-hydrates, proteids, and phosphates in most assimilable form. These principles, together with cod liver oil deprived of all its disadvantages, render "Maltine" with Cod Liver Oil a most successful reconstructive agent, and explain its long and extensive employment by the Medical Profession.

The BRITISH MEDICAL JOURNAL reports:—"The therapeutic value has been so thoroughly recognised and is so well known. ..... Patients unable to tolerate the purest and most carefully prepared cod liver oil can readily digest and assimilate it when combined with 'MALTINE.'"

LIST OF "MALTINE" PREPARATIONS.

"MALTINE" Plain.
"MALTINE" with Coca Wine.
"MALTINE" with Cod Liver Oil.
"MALTINE" with Iron.
"MALTINE" with Pepsine and Pancreatine.
"MALTINE" with Lime (Hypophosphites).
"MALTINE" with Cascara Sagrada.
MALTO-CARRAGEEN.
"MALTINE" with Phosph. Iron, Quinia, & Strychnia.
"MALTINE" with Phosphates.

In Bottles, containing 8 and 16 Fluid Ounces, and Winchester Quarts.

The word "MALTINE" is our Registered Trade Mark. In prescribing, kindly specify "MALTINE COMPANY."

We shall be pleased to send Samples free of charge to Medical Men.

THE MALTINE MANUFACTURING COMPANY, Limited,

An Address
ON
ACQUIRED IMMUNITY.

BY G. ARCHDALL REID, M.B.EDIN.

GENTLEMEN,—Against some zymotic diseases—e.g., small-pox and measles—an average individual is able, through illness and recovery, to acquire life-long immunity; against other diseases—e.g., diphtheria and relapsing fever—immunity may be acquired, but is of limited duration only, and in a shorter or longer time the individual, lapsing his acquired powers of making resistance, becomes as liable to infection as ever he was; against a third class of diseases—e.g., tuberculosis and leprosy—immunity can never be acquired; in other werds, experience of such diseases never confers on the sufferer increased powers of making resistance even for a limited time, whence it follows, as a corollary, that such diseases may persist in the individual for a length of time that is only limited by the duration of his life, no matter how long that may be.

Now it is very noteworthy that it is only against diseases the micro-organisms of which produce more or less powerful toxins—as judged by their systemic effects—that immunity can be acquired. When the toxins are feeble or non-existent—e.g., in tuberculosis and leprosy,—when the onset of the disease is unmarked by symptoms of poisoning, when the pathogenic micro-organisms, instead of engaging at long range, enter at the outset into what may be termed an actual physical struggle with the phagocytes, which, undeterred by toxins, at once attack the disease germs, and taking them into their substance attempt to destroy them, then immunity cannot be acquired. Malaria is an apparent exception to this rule, for here the toxins are undoubtedly powerful, yet immunity seemingly can never be acquired; but it seems probable that this disease should rather be regarded as one against which more or less complete immunity is very rapidly acquired and as rapidly lapsed, for thus only can we explain the alternations of extreme illness, during which the parasites are abundant in the blood, with comparative health, during which they are absent or almost absent from it, and when such of them as still survive the assault of the phagocytes probably exist in a comparatively harmless but highly resistant form—e.g., as resting spores. Moreover, the completeness with which immunity may be produced against any disease, though not its duration, seems, generally speaking, in direct proportion to the quickness with which the toxins are produced and to their degree of virulence. The duration of the immunity depends on factors of which we have as yet no knowledge; but it seems more than probable that it is determined by the chemical constitution of the toxins in each disease. It is clear, then, whenever immunity can be acquired against any disease, that it is associated as effect and cause with the fact that in any such disease more or less potent toxins are always present. In a recently published work[1] I endeavoured to show why this must necessarily be so; but recent though the work is, still more recent researches, especially those in snake venom by Professor Calmette and Professor T. R. Fraser, render necessary further developments and emendations of the hypothesis set forth in it—a hypothesis that is founded on Metchnikoff's famous theory of phagocytosis.

Different inquirers have propounded different theories of *rationale* of acquired immunity. It has been supposed (Pasteur) that the pathogenic micro-organisms of each disease against which immunity may be acquired find, every species of them, some special pabulum on which they subsist, but on which no other species subsist, and that when this special pabulum is exhausted they perish from starvation. In diseases against which acquired immunity is usually permanent—e.g., small-pox—this pabulum, it was supposed, is usually not renewed; but when immunity is not permanent—e.g., diphtheria—it is renewed, whereby the individual once more becomes susceptible. Again, it has been supposed (Chauveau) that acquired immunity arises because the waste products of micro-organisms are inimical to their own life, as alcohol is to yeast; and, therefore, when this reaches a certain percentage in the fluids of the host the micro-organisms perish, as yeast perishes when alcohol reaches a certain percentage in a solution of sugar. In diseases against which acquired immunity is permanent it was supposed by this theory that these waste products are permanently bottled up within the host, but that they are eliminated after a time in diseases against which immunity is not permanent. Both these hypotheses are negatived by the fact that the micro-organisms of certain diseases—e.g., anthrax—are able to flourish in the blood serum of animals that have acquired immunity against them. Metchnikoff's theory supposes that certain cells of the body known as phagocytes attack and destroy the micro-organisms when they find entrance, and that when toxins are present these cells acquire powers of resisting or ignoring them; and, further, when immunity is permanent such powers are permanent, but when immunity is only temporary they are after a time lapsed.

It is now beyond dispute that phagocytosis does occur. All that is in dispute is whether it is the sole or even the principal cause of immunity. More recently Behring has propounded the theory, which received very general assent, that acquired immunity is due to the elaboration by the host of specific antitoxic substances which chemically neutralised or antagonised the specific toxins as an acid is neutralised by a base. Lastly, Fraser[2] and others, modifying Behring's theory, have surmised that the antitoxins are constituents of the toxins, or else by the action of the host are produced from them, and, like Behring, Fraser thinks that they chemically neutralise the toxins. The theories of Pasteur, Chauveau, and others which it is needless to mention, had their day, but are now known to be erroneous. Metchnikoff's theory was in vogue for some years, but lately seems to have passed somewhat into the background; whereas Behring's theory, or modification of it, like Fraser's, appears so well to fit many of the ascertained facts, especially those most recently ascertained, that they are now largely accepted. In particular, Behring's theory appears to be in accordance with his own highly important discovery that if the toxins of a pathogenic organism be injected in proper quantities and for a sufficient length of time into the body of one of the higher animals the blood serum of this animal acquires specific antitoxic properties; that is, a given quantity of it tends to neutralise or render harmless given quantities of the toxins of that particular organism, not only when the substances are mixed *in vitro*, or when they are injected separately into the body of another and a susceptible animal, but also during the course of disease, when the specific toxins are produced within the body, and the specific antitoxin alone is injected; while they do not neutralise or render harmless the toxins of any other species of micro-organisms. But apart from the inherent improbability that the animal body is a species of magic bottle, producing at need highly complex chemical substances, the so-called antitoxins, which exactly neutralise or antagonise other highly complex chemical substances, the toxins, the right antitoxin at the right time, as Behring thinks; or that the toxins contain, or are capable of being converted into substances chemically antagonistic to themselves, and to no other toxins, as Fraser thinks, there are certain facts known to us concerning various diseases which prove that neither theory, even if correct, offers a complete explanation of all the facts, while a closer examination furnishes solid grounds for doubting whether either offers a correct explanation of any of them.

For instance, Pasteur killed rabbits suffering from rabies and dried their spinal cords. His treatment for the cure of an infected subject consisted in the injection into him of an emulsion from an old and thoroughly desiccated cord, was continued by injections from fresher and fresher cords, and ended by the injection of an emulsion from a cord that was absolutely fresh and virulent. By these means he enabled many individuals, who already had been infected, and would otherwise have perished, to acquire immunity. It is clear that the immunising agent, the "antitoxin," is here produced in the dead and drying cord, not in the living infected animal from which the cord was taken, since in the latter case such an animal would not perish if left to itself, as it invariably does, and since the immunising substance is procurable from old and dried cords and not from those which

are absolutely fresh. It is therefore not produced by the vital action of the cells, but arises in the absence of all vital action in a dead thing. No doubt chemical changes do occur in a desiccating cord, but it would be strange if these resulted (1) in substances chemically antagonistic to the particular toxins and to no other, or (2) in the conversion of the toxins into substances chemically antagonistic to themselves, or (3) in the destruction of the toxic portion of the poison while a hypothetical antitoxic portion was left unaltered. Again, by submitting the bacilli of anthrax to an abnormal degree of heat (from 42° to 43° C.), Pasteur found that they gradually lost their virulence, and found, moreover, that if sheep were inoculated first with bacilli of little virulence, next with those of greater virulence, and lastly with bacilli of great virulence, the animals could be rendered immune to bacilli of the greatest virulence, and could thereby be protected against the disease. In this case the bacilli are introduced alone or with an insignificant amount of toxin. The "antitoxins," whatever they may be, are elaborated within the sheep, and it is difficult to understand, if they are substances chemically antagonistic to the toxins, why they should be elaborated only when the animal has undergone such treatment and not otherwise. Again, if we pass the virus of small-pox through a series of calves, the organism producing that disease becomes so "attenuated" that if a human being is vaccinated from the calf there results not variola but vaccinia. In this case, as in vaccination against anthrax, only the attenuated micro-organism, with at most an infinitesimal amount of its products, is introduced, yet the result is that the powers of resisting the graver disease are acquired. Here, again, chemical neutralisation cannot possibly play a part. Lastly, the micro-organisms of certain diseases (e.g., malaria) vary greatly in virulence, sometimes being productive of a very grave disease, and at other times of a much milder disorder.[3] To this category belong the bacilli of diphtheria, and it has been found in German hospitals when, owing to the difficulties in the way of efficient nursing during a widespread epidemic, mild cases were admitted among the graver cases that the latter showed a greater tendency to mend than had been observed before. Here, also, the production of chemically antagonistic substances can hardly have had anything to do with the improvement; but we may well believe that in this case also the improvement was due to attenuated bacilli from the milder cases finding their way to the severer, where their weaker toxins furnished stepping stones for the attainment of resisting power against the stronger.

Now these facts and many others, as we shall see, are in full accord with Metchnikoff's theory, but are not at all in accord with Behring's. We may believe that in the drying cord of the hydrophobic rabbit, in the abnormally heated anthrax culture, in the calf infected with the organisms of small-pox, in the mild diphtheritic cases, the pathogenic organisms are so altered that they produce enfeebled toxins, and that by these enfeebled toxins the cells (probably the phagocytes) of the infected animal are so inured, so educated, that they are able to resist the stronger toxins of the normal microbes and to destroy the pathogenic organisms producing them; but it is at the least a gratuitous assumption to suppose that micro-organisms, which have been attenuated or constitutionally modified by subjection to a changed environment, produce secretions chemically antagonistic to those which they produce in their normal surroundings, or, on the other hand, as the only alternative, that the infected animal produces them the more readily for previous experience of these attenuated toxins. The process whereby the infected animal acquires immunity, whereby it becomes so modified that it is able with comparative ease to resist the effects of toxins which before it was incapable of resisting, or could have resisted only with difficulty, is after all no miracle, but only a particular manifestation of that power of acquiring a multitude of fit traits by means of which high animal organisms place themselves in harmony with their enormously complex environment. I have dealt at length with this interesting question of acquired traits elsewhere.[4] It is needless to repeat arguments which, as far as I am aware, have received general assent. It suffices to remark that while such a phenomenon as the production by pathogenic micro-organisms in a changed environment of toxins which are chemically antagonistic to those which they normally produce, or the production by an infected animal of antitoxic substances chemically antagonistic to the toxins of the microbes by which it is assailed, has no parallel in nature, that process of adaptation by means of which, as I here suppose,[5] the phagocytes or the other cells concerned are gradually so modified constitutionally that they are able to resist microbic poisons which before they were unable to resist has innumerable parallels. Thus, for instance, if the mucous membrane or the external skin be subjected to intermittent heat or friction or the action of chemical irritants, the cells of it become so modified, both as regards quality and numbers, that they become capable of resisting degrees of heat and friction, &c., which would otherwise injure or destroy them. Thus, also, muscle cells, under the influence of intermittent exercise, acquire additional powers of resisting fatigue. But the closest parallels are furnished by the increased powers of resistance which man is able to acquire against various poisons—for instance, arsenic, opium, and nicotine (the last two being to all intents and purposes toxins, since they protect the organisms producing them against other organisms to which these are liable to fall a prey). Here again we may well believe that the cells concerned (nerve cells, &c.) become, through experience of these poisons, so constitutionally modified that at length they are better able to resist them when presented in larger and more concentrated doses than before they were able to resist them when presented in weaker doses. I suppose that no one will maintain that increased resistance to opium, arsenic, or nicotine results from the manufacture of a substance antitoxic to these poisons. Yet it would be as reasonable as to suppose that immunity from rabies, anthrax, or small-pox results from similar causes. I think, then, we may fairly conclude that (in the cases cited at least, and probably, as we shall see, in all others) the essential feature of acquired immunity (or increased powers of resistance) is an habituation of the cells concerned to the toxin, as a result of which their phagocytes are able to destroy the pathogenic micro-organisms producing it; and, further, in cases where the toxins are very poisonous, that this habituation, this power of ignoring the toxins and destroying the microbes, is more easily achieved (just as other acquired traits are more easily achieved) gradually, by a series of efforts than at once by a single effort, so that in such an extreme case as rabies, when the toxins are so virulent that normally reaction to them is impossible, immunity may be obtained by subjecting the animal first to weaker and then to stronger toxins, till at last it is able to resist even the strongest toxins, and so escape an otherwise inevitable death.

The principal objections to this view have origin in Behring's discoveries, and from them have resulted his theories and such modifications of them as Fraser's. It was found by him that if toxins—e.g., those of diphtheria—be injected into a living animal—e.g., a horse—beginning with small non-lethal doses and proceeding at intervals to stronger and stronger lethal doses, that the animal experimented on not only acquires immunity against the disease and powers of resisting enormous doses of the toxins, but also that its blood serum (1) when injected into an animal susceptible to the disease tends to render it resistant, just as progressive doses of toxin would (2) when injected into an animal already suffering from the disease tend to bring about a cure, and (3) when injected before or at the same time, or shortly after the toxin, or when mixed with the toxin *in vitro* previously to injection, tends apparently to neutralise or antagonise the toxin; so that, especially in the last case,[6] doses of the toxin much larger than those which are ordinarily lethal can be borne with impunity. Moreover, Fraser found that if snake venom be swallowed, as it may be, in enormous quantities without injury, that then also the animal experimented on acquires immunity and its serum antitoxic properties. In all these instances it was found that the acquired powers are specific—that is, experience of the toxins of any disease confers immunity against that disease alone and not against any other, while the resulting serum also confers immunity against, has curative powers against, and antagonises the toxins of that disease and no other.

Metchnikoff's theory furnishes an explanation of the increased powers of resistance to any toxin which experience of it confers on the serum producer. In this case, as in disease, we may suppose that the cells concerned become

[3] Vide Present Evolution of Man, pp. 239-40.
[4] Ibid., pp. 114-19.
[5] A view first set forth by Tizzoni and Cattani.
[6] At least, so Fraser alleges, though his statement appears now to be disputed.

Digitized by Google

habituated to the toxins, hence the high degree of resistance. But the theory as set forth above is totally inadequate to account for the rest of the phenomena just detailed. Presumably the antitoxic serum contains toxins in solution. It follows, then, that this serum, instead of conferring immunity or antagonising the toxins, should add to the effect of them by increasing the dose. The fact, however, is the reverse, for it clearly does confer immunity and apparently also, judging from the experiments *in vitro*, it does antagonise the toxins. Except, then, these difficulties are surmounted we must abandon the theory which supposes that increased powers of resistance are due to increased powers of toleration.

The key to the mystery is probably furnished by Fraser's experiments. We have seen that snake poison may be swallowed in enormous quantities, when, so far from causing death, it actually confers some degree of immunity on the animal swallowing it and some degree of immunising power on his serum. Fraser, indeed, conjectured "that the venom while in the stomach had been subjected to a process of analysis by which the constituents which are poisonous had failed to be absorbed into the blood or had been destroyed in the stomach, while the constituent or constituents which are anti-venomous, or rather antidotal, had passed into the blood in sufficient quantity to protect the animals against otherwise lethal administrations of the venom."[7] But this conjecture seems very improbable and far-fetched. On biological grounds it is highly improbable, to say the least, that snake venom contains a substance antidotal to itself—i.e., that the animal's weapon of offence and defence has combined with it a substance which enfeebles it. Again, it is not in accordance with known facts that the alimentary canal possesses the power of intelligent choice which Professor Fraser attributes to it, by virtue of which it accepts the good and rejects the evil. The function of the canal is digestion; and surely, since animals are not poisoned by huge doses of swallowed venom, we are entitled to assume that the venom, like other proteids, undergoes digestion; and, further, since the swallowing of venom confers on the animal increased powers of resisting the injected poison, and on its serum antitoxic properties that these effects are due to a reaction, induced by the altered, the attenuated, the digested toxins, of a similar nature to that induced by other altered and attenuated toxins—e.g., those of rabies, anthrax, or small-pox. If this be admitted, as I think it must, then we arrive at the conclusion, of great importance in our inquiry, that here the venom is attenuated by ferments secreted by cells lining the alimentary tract, not by the cells themselves—that is, by ferments which digest the toxins extra-cellularly, but are innocuous to the cells themselves.

Now, phagocytosis itself, whether in low unicellular or high multicellular organisms, is nothing other than a process of digestion—i.e., the cells destroy the micro-organisms which they have taken up, not by mechanical means, by pressure, or by tearing, but, as cannot be doubted, by digestive substances which they secrete, and it has been further proved that they are capable of performing the digestive act, not only intracellularly, but like the stomach cells or the cells of the pancreas and the salivary glands extracellularly also. For instance, Metchnikoff found that when the gregarines which infest the male genital organs of the earthworm become passive previously to spore formation they are attacked by wandering cells which form a thick plasmodium round them. The parasite on its part forms a thick cyst-wall, but nevertheless frequently undergoes degeneration and death. Kanthack and Hardy found that when anthrax bacilli are introduced into frog's blood "the coarsely granular oxyphile cells act as unicellular glands, discharging or secreting their granules, and these granules dissolving appear to exert a deleterious action on the bacilli, in consequence of which the hyaline cells are now capable of ingesting them."[8] Other inquirers have made observations of a like tendency. And it has also been found that intruding micro-organisms perish when at a distance from the cells as well as when they are ingested, or when the cells are applied closely to them. Thus Nuttal, on introducing a fine cannula containing attenuated anthrax bacilli into a rabbit's ear, found that phagocytosis reached its maximum after twenty-two hours, but that even then half the bacilli lay free and not ingested by the phagocytes, but exhibited nevertheless as much signs of degeneration as those which had been ingested. Thus also it has been found that during recovery from diphtheria and pneumonia numbers of the pathogenic microbes perish without direct conflict with the cells. It is not too much to assume that the same agent causes the death of free microbes as that which causes the death of those which are actually ingested or those to which the phagocytes are directly applied. In other words, we have good reasons to believe that they perish by reason of a digestive substance secreted by the cells and set free into the fluids of the body, just as pepsin is set free in the fluids of the stomach. Direct evidence of the presence of this digestive substance was furnished by Leber, who placed pieces of copper in the anterior chamber of the eye, producing a purulent collection devoid of micro-organisms, the exudate from which was capable of digesting proteid matter. This, then, since it is highly improbable that there is one substance which destroys the bacilli at close quarters and another which destroys them at long range, is probably the germicidal substance found in the plasma and the serum of immune animals. But of course the digestive substance must be in greater concentration within the cells producing it and in their immediate neighbourhood than at a distance, and therefore it must act more effectively in the former than in the latter case. On the other hand, the toxins produced by the microbes must also be in greater concentration, and must act more effectively on objects in their immediate neighbourhood, and especially on those with which they are in actual contact, for which reason, doubtless, it is that micro-organisms which do not produce toxins, or produce only feeble toxins—e.g., those of leprosy and tuberculosis—are at once attacked and taken up by the phagocytes, while micro-organisms which produce strong toxins—e.g., those of anthrax and diphtheria—are not taken up till a later period, when the phagocytes have become habituated and resistant to the toxins, or even are not taken up at all, but are engaged only at long range. It is probable that the digestive substance produced by the cells is normally present in them, but that its secretion is greatly accelerated by the presence of certain foreign bodies in the blood—e.g., bacteria and their toxins.

But besides the germicidal substance there is irrefragible evidence proving that in the blood of an infected but resistant animal, or in that of a resistant animal into which toxins have been injected, there is present another and probably a distinct substance[9] which destroys or renders inert the toxins; and, reasoning from analogy, this also in all probability is a digestive substance. The commonly accepted theory is that it is a substance which chemically antagonises the toxins; but such a view commits us, as we have seen, to the belief that all the separate toxins of the separate diseases are separately antagonised by different antitoxins—a belief hardly reasonable when we consider the multitude of the diseases and the complex chemical nature of their toxins. On the other hand, it is by no means incredible that a single digestive body is capable of digesting all these "toxalbumins" just as pepsine is capable of digesting a variety of proteid substances, or even that there are two or three different digestive bodies which severally digest the toxic albumoses, globulins, peptones, &c., which the different species of pathogenic micro-organisms produce. Moreover, this antitoxic substance is very rapidly produced, since it has been found in blood drawn from a rabbit's ear immediately after the introduction of the toxin, this seems still further to confirm the view that it is a digestive body; for while appropriate stimulation (that from a toxin) might well cause its rapid secretion by cells that manifestly do perform digestive functions and otherwise closely resemble their remote amœboid ancestors, it is unlikely, not to say impossible, that these cells can instantly elaborate the right chemically antagonistic substance when they are assailed by this or that toxin, especially when the toxin is produced by a microbe of which their ancestry can have had no experience, and against which, therefore, no specific powers can have been evolved. I think we may fairly conclude, then, that the destruction or attenuation of toxins which occur in the body of a resistant animal is due to their digestion by an enzyme secreted by

[7] *Vide* Nature, April 23rd, 1896.

[8] Adami: A System of Medicine, by Many Writers, p. 91.

[9] This would appear from Klein's experiments. That observer found that if pure toxins were injected in sufficient quantities into a horse the serum acquired a high antitoxic but comparatively low germicidal power, whereas if bacilli were injected the reverse occurred. Fränkel claims to have separated the antitoxic from the immunising substance by heat.

Digitized by Google

cells that have that special function, and it follows, if this view be true, that when a resistant animal is recovering from a disease in which toxins are abundant, or when repeated doses of toxins are injected into a resistant animal, there must be present in his blood and in his serum when drawn off, firstly, two or more digestive substances, and, secondly, *toxins in all stages of digestion*.

Now we saw when considering Pasteur's experiments that powers of resistance against virulent toxins and the micro-organisms producing them—i.e., against the disease—are much more readily attained by a series of efforts than by a single effort; in other words, immunity is much more readily achieved if the cells concerned have presented to them the toxins in a graduated scale, beginning with toxins of a low degree of virulence and ending with those of a high degree of virulence, in this resembling other kinds of cells when concerned with other deleterious influences—for instance, the cells concerned when nicotine is taken into the system, which are able through habituation to tolerate without injury enormously increased doses. But while there is this general resemblance in the reactions induced by graduated toxins and graduated deleterious influences of other kinds there is a very important difference—viz., that in the presence of large doses of nicotine, arsenic, opium, &c., smaller doses add to the effect of the larger, whereas in the presence of virulent toxins, less virulent toxins do not add to the effect of the former, but, on the contrary, often induce a protective reaction against them. This, for example, we find is the case when attenuated injections from a series of drying infected cords are made into an animal suffering from rabies, in which disease there is present a microbe that produces toxins of such extreme virulence that normally no reaction is possible against them any more than against fatal doses of arsenic, opium, &c., so that the infected animal invariably perishes except the protective injections be made. The explanation of this remarkable phenomenon is probably to be found in the fact that while larger and smaller doses of arsenic, opium, nicotine, &c., are but degrees of the same thing—are but the same thing in different amounts and degrees of concentration—stronger and weaker toxins are not the same thing in different amounts and degrees of concentration, but strong toxins differ somewhat in kind from the weak toxins of the same disease, are probably of a somewhat different chemical constitution, and therefore while moderate heat, friction, fatigue, or doses of nicotine, &c., in the presence of greater heat, friction, fatigue, or doses of nicotine, &c., cannot inure the cells concerned to the action of the latter, the weaker toxin can sometimes, even in the presence of the stronger when these are not too concentrated, inure the cells concerned to the action of the latter, as in the case just cited of an individual already infected with rabies when attenuated toxins are introduced from a slowly drying cord in an early stage of the disease. At a later stage, when the strong toxins are more concentrated, it is useless to inject the weaker, for the poisoned cells are then unable to react and the animal perishes. This view is confirmed by a study of other diseases. In diphtheria, for instance, the pathogenic micro-organisms are limited to a small area of the surface; the toxins are, therefore, in the earlier stages at least, very dilute in the blood, and as a consequence it is often possible to introduce attenuated toxins with advantage, whereas in small-pox, in which the micro-organisms presumably pervade the whole body and the toxins are from an early period concentrated, it is useless to vaccinate after the first symptoms of the disease have appeared.

Apparently, then, acquired immunity consists essentially of an acquired power of tolerance, by virtue of which the cells concerned are able to perform their functions in spite of the presence of toxins. In the case of the cells specially concerned in zymotic diseases—i.e., those concerned in the destruction and removal of the pathogenic micro-organisms and their toxins—this acquired power enables them the more readily to produce the two or more digestive bodies inimical to the ferments and their toxins. But if an animal which has not acquired immunity (in the case of diseases against which permanent immunity may be acquired), or which has lapsed its acquired immunity (in the case of diseases against which permanent immunity cannot be acquired), be infected, then the cells concerned being poisoned may not react at all—i.e., may fail to produce their digestive bodies, when the proliferation of the invading microbes and the elaboration of their toxins will continue unchecked, and the animal will perish; on the other hand, in an animal which has not acquired immunity, or which has lapsed its immunity, the inborn powers of resistance of the cells may be, and is, as regards most animals in relation to most diseases, so great that they are able to produce the digestive bodies to some extent from the first in spite of the presence of the toxins, and therefore most animals are capable of recovering from most of the diseases to which they are liable. Digestion—i.e., attenuation—of the toxins then occurs, till in time there are present in the animal's blood toxins in all stages of digestion, from virulent toxins newly produced, and hardly affected by the enzymes, to toxins long produced, and so enfeebled as scarcely to deserve the name; and, as reasoning by analogy we may suppose, *up that graduated scale it is probable the cells of the animal react till complete immunity is attained*, just as the cells of an animal affected by rabies and anthrax react when treated to the less finely graduated toxins provided by Pasteur's treatment.

Moreover, if the blood serum of such an animal be removed and injected into a susceptible subject, either one not yet infected, or, if infected, one the cells of which are not poisoned beyond the power of reaction, this second animal also will thereby be provided with a means of achieving immunity. If he be not infected the altered toxins will provide him with a scale of graduated poisons up which his cells may react towards complete immunity, the completeness of the immunity acquired by him being proportionate to the virulence of the toxins at the more poisonous or least digested end of the scale. If he be already infected, not only will the injection provide him with a scale of graduated toxins, but it will also provide him with digestive bodies wherewith to attenuate the toxins which are then being elaborated by the micro-organisms infecting him. But of course the blood serum of an animal which has been infected and is recovering from the disease will be infinitely inferior in curative and immunising power to the serum of an animal into which the large quantities of toxin (elaborated in an artificial medium) have been injected in oft-repeated doses extending over a length of time, since in the latter case the quantity of attenuated toxins and digestive bodies will naturally be much greater than in the former. It further follows that, if we mix toxins with fresh antitoxic serum *in vitro* at a suitable temperature and for a sufficient length of time, the digestive bodies present in the latter will attenuate the former, and, therefore, that much larger doses of toxins can be administered without death in this way to a susceptible animal than in any other. Professor Fraser contends that, since antitoxic serum when mixed with toxins *in vitro* "neutralises" the latter more effectually after twenty minutes' contact than after contacts of five minutes, proof is thereby supplied or a probability raised that such a neutralisation is a chemical one in the sense meant when we say that an acid is neutralised by a base; but surely when we remember the comparative rapidity of chemical and the comparative slowness of physiological reaction the probability is that we have here to deal with a digestive process rather than a mere chemical combination, a probability immensely strengthened by the considerations already dwelt upon that it is hardly likely that the animal body is a magic bottle producing at need the right toxins on the right occasion.

Various other considerations lend strength to the belief that acquired immunity against any disease depends essentially on a gradual habituation to its toxins, or an increased power of physiological resistance, as a result of which cells are enabled to perform their functions in spite of the presence of the toxins (which indeed do then but stimulate the cells specially concerned—i.e., those which produce the digestive bodies), not on the production of chemically antagonistic substances; and further that the persistence of immunity depends on the persistence of this power, not on the continued persistence within the system of antidotal substances, whether chemical (in the narrow sense) or digestive. For instance, it was found by Roux and Vaillard that, if too large or too frequent doses of tetanus toxin are injected into the horse, the antitoxic powers of the serum disappear for a time, and the serum actually becomes toxic; yet the horse manifests no symptoms of tetanus, as it would did immunity depend on the production of chemically antagonistic substances and not on a habituation to the poison. In this case it is evident that the cells of the horse are unable to produce digestive bodies fast enough to quickly attenuate the excessive quantity of toxin. Again it was found by Buchner that a mixture of toxin and

Digitized by Google

antitoxin—e.g., that of tetanus—in a proportion harmless to an animal of one susceptible species—e.g., a mouse—is still toxic to a weaker animal of the same species or to an animal of a more susceptible species—e.g., a guinea-pig—which could not be the case did the antitoxin contain substances which neutralised the toxin; whereas, if immunity depends immediately on a physiological, not on a chemical, reaction, even an attenuated toxin may be fatal to a very susceptible animal; an inference corroborated by the fact that a non-susceptible animal may be rendered susceptible by influences—e.g., cold or starvation—which lower the vitality.

But, perhaps, the most beautiful and convincing proof is supplied by the study of syphilis, a disease against which immunity may be acquired, but which, owing to the feebleness of the toxins (in this approaching tuberculosis and leprosy), yet persists long enough in a woman to cover the entire period of pregnancy. Normally, as we know, there is no connexion between the placental blood-vessels of a mother and those of her fœtus. But they are in close apposition, and are very thin-walled, so that while solids (e.g., the microbes of disease) are normally stopped, fluids with gases and solids (e.g., toxins) in solutions pass from one to the other by diffusion. Under abnormal circumstances (e.g., during disease) the continuity of the vessel-walls may be broken, and then solids as well as fluids pass from one to the other. It can hardly be doubted that this is what commonly happens in syphilis, and therefore a syphilitic mother very generally bears a syphilitic child. But when in rare cases the continuity of the vessel-walls is not broken, when a syphilitic mother bears a healthy child, or when, as more commonly happens, the healthy partner of a syphilitic father is delivered of an infected child, then is seen a most instructive phenomenon—the healthy individual is seen to be immune to the disease, for such an infant does not acquire the disease when suckled by his infected mother, nor, on the other hand, as Colles proved, does a healthy mother contract the disease when suckling her infected child, though other women do. Here during gestation toxins, passing from the infected to the non-infected individual, inure the cells of the latter to resistance, and as a result they destroy the pathogenic micro-organisms, if at any future time, in the act of sucking or of giving suck, they find entrance. But the children born of a mother who has recovered from syphilis, and who is immune, are not themselves immune, as are the healthy children born to her during her illness. Whence it follows that her continued immunity is not due to the presence of chemical antidotes or digestive bodies; for if it were her offspring would continue to be born immune, just as they did (if uninfected) when she was ill. Her continued immunity is plainly due to the fact that her cells do not lapse the training they received when she was suffering from the disease.

In connexion with syphilis it would be interesting to seek the explanation of some instructive phenomena which often occur in the inherited form of that disease. If a man contracts syphilis then, after a certain number of years, of which the limit has been set at five, he ceases as a rule to be infective to a woman, but for very long after he may have offspring who exhibit all the signs of very virulent infection. If a woman contracts syphilis, then, like a man, she also ceases after a limited time to be infective to another adult, and not only this, but, unlike the man, she ceases also to be infective to her children (Diday's law of decrease). Speaking only in general terms and without regard to the numerous exceptions, which doubtless depend on differences in resisting power in the offspring, the children earliest born to her after infection suffer in the absence of treatment most severely from the disease, those later born less severely, till at length, if she continue to bear children, the latest born do not suffer at all. Her disease tends at first to result in abortions and miscarriages, then in the birth at term of one or more dead children, then in one or more children who survive their birth for a space, next in children who survive, but show signs of disease, and, lastly, in children who show no signs of infection. If such a woman mate with an infected man this law still holds, for which reason the children of a married couple who have the disease, as a rule, even in the absence of treatment, show less and less signs of it, whereas a woman not previously infected may bear grievously infected children to a father who has long ceased to exhibit signs of the disease. Moreover, if a non-infected mother bear infected children, who live, to a diseased father, her children also show less and less signs of it, until at length they show no signs at all.

If I am right in the foregoing part of this paper, acquired immunity to syphilis, like acquired immunity to other zymotic diseases, must depend on an acquired power of tolerating the toxins, the cells concerned (especially those concerned in the elaboration of the digestive bodies) being able to perform their functions in spite of the presence of the toxins, in consequence of which the micro-organisms must gradually be destroyed, or if some of them survive they must survive in the unfavourable environment in a highly resistant, and, therefore, judging by analogy, a very harmless form—e.g., as resting spores. Now we have evidence that pathogenic micro-organisms do not induce disease in susceptible animals when the number in which they find entrance sinks below a certain minimum, which minimum doubtless varies with the species of the invading microbes, with the species of the animal attacked, and even with each individual of the latter. Thus it has been found that to kill a rabbit by artificial infection at least 16,000 virulent anthrax bacilli must be introduced, a lesser number, if introduced, perishing and the rabbit acquiring greater resisting powers (Lubarsch). Again 1 c.c. of a fresh broth culture of bacillus pyocyaneus will infallibly cause fatal disease in a rabbit, which, however, will survive and acquire increased resisting power from the injection of a quarter of that quantity. But immature animals are less resistant than adult animals of the same species;[10] for instance, young guinea-pigs succumb more easily to attenuated anthrax bacilli than do older animals. Presumably, therefore, young animals are capable of being infected by a smaller quantity of microbes than adults, and for this reason it probably is that a father may infect his offspring with syphilis at a time when few microbes survive in him, and long after he has ceased to be infective to a woman; and this readier infectibility of the young probably suffices also to explain the fact that while it is rare for a diseased woman to bear a non-infected child, it is much more common for a diseased child to be born of a healthy mother. Moreover, both the ovum and the spermatozoon are unicellular animals; in them there is no differentiation of tissue for the performance of different functions; in them, therefore, are no cells which can react to the toxins, and therefore neither ovum nor spermatozoon has the power of resisting the microbes, or in other words of acquiring immunity. This power, like the power of acquiring all other acquirable traits, arises later in their cell-descendants when these latter have undergone morphological and physiological specialisation and differentiation into skin, muscle, gland, nerve, phagocytic and other cells. Hence it follows that a man can never confer immunity on his children, for though his spermatozoa be bathed in toxins they cannot react, since the necessary machinery is wanting. So, also, a woman who has recovered from syphilis or any other disease cannot, then, confer immunity on her non-infected children, for though during her illness her ova are bathed in toxins, yet in them also the machinery for reaction is wanting. But if a woman become pregnant during her illness, then in her embryo (that mass of the adherent cell-descendents of her ovum) there are present differentiated and specialised cells, which, like those of her own body, have the power of acquiring various traits, among others that of reacting to the toxins of this or that disease. And, therefore, while a man can never confer immunity on his children, or a woman on children born to her before infection or after recovery, a woman can confer immunity on offspring of which she is pregnant during her illness, for in the latter case the necessary machinery for acquiring immunity is present—i.e., the toxins passing from the mother to the embryo may induce a protective reaction in the cells of the latter, especially in those concerned in the elaboration of the digestive bodies.

But syphilis is a disease of long duration; in other words, immunity against it is only very slowly acquired—that is, the cells only very slowly acquire the power of tolerating the toxins, and of producing the digestive bodies undeterred by their presence. It follows that if a woman become pregnant during the earlier stages of her illness, even if the microbes be stopped in the placenta and the child is not affected, there will pass from her to the embryo toxins which are little or not at all attenuated, and therefore since young individuals are in general less capable of resisting zymotic diseases than the older members of their species the embryo perishes, and the mother aborts or miscarries. But as her

[10] For the biological explanation of this see The Present Evolution of Man, p. 269.

Digitized by Google

disease progresses the mother gradually acquires more resisting power; her cells become more and more tolerant of the toxins, and therefore more and more capable of producing digestive substances which attenuate and destroy the toxins, and therefore up to the time of her recovery she becomes more and more capable of conferring immunity on her offspring, since as time lapses there pass from her to the child toxins in greater and greater states of attenuation. Then, even if the child be infected (as usually occurs), the digestive substances he receives through the placenta from the mother tend to destroy the micro-organisms and attenuate the toxins produced in him. At length, before recovery and immunity are achieved, a time arrives, the advent of which varies in different individuals, when the digestive substances produced in the infected mother are of such potency or in such abundance that the toxins are so much attenuated as not to destroy the child, who is then born alive, and he may be of a fat and healthy appearance.[11] In him are present digestive substances, attenuated toxins, and the micro-organisms of the disease. Frequently in such a child the disease reasserts itself, the child begins to pine and ere long perishes. The only feasible explanation of this phenomenon appears to be the following: that the digestive bodies from the mother attenuate the toxins sufficiently to protect the child from injury, but not sufficiently to bring about in the young individual a protective reaction, which is then as impossible to him as a protective reaction to the non-attenuated toxins of rabies is to an adult individual. Therefore, after birth, when the digestive bodies derived from the mother are exhausted, the toxins produced by the microbes within the child, and not now altered, cause his death. But in a still later stage in the mother's disease the toxins are so much attenuated that the cells of the child are able to react, and, therefore, though after birth signs of the disease may be seen, he recovers and is afterwards immune. Still later, when the mother has recovered, when her cells have acquired the power of resisting the toxins and she is immune, the child can acquire from her neither the disease nor the immunity, since toxins, attenuated and otherwise, no longer pass from the one to the other.[12]

On the other hand, if a healthy mother bear diseased children to an infected father we should, if our theory be correct, expect to find (and actually we do find) that each succeeding infant exhibits less and less signs of the disease, and this notwithstanding the fact, other things being equal, that the last child infected by a diseased father tends, when born to a different woman who has not previously suffered from the disease or borne infected children, to have the complaint as deeply as the first; in other words, a woman who has once borne an infected child tends to endow succeeding infected children with greater and greater powers of resistance, the greater powers of resistance being clearly derived from her and not from the father, since other women who have neither themselves been infected nor have borne infected children may bear deeply diseased children to the same father. Here in the case of the former woman toxins from each infected child pass into the circulation of the non-infected mother, inducing a more and more perfect reaction in each succeeding pregnancy; and therefore in each succeeding pregnancy there are elaborated by her more and more digestive bodies, which at length attenuate the toxins so thoroughly that the cells of the child are able to react and the child survives, instead of perishing in intra- or extra-uterine life like its predecessors. In this case toxins pass from the child to the mother, while from the mother to the child pass attenuated toxins and digestive substances.

It follows as a corollary that, if a mother who has acquired immunity either by personal disease or by bearing infected children become pregnant of an infected embryo, she will tend to confer immunity on the embryo, since the elaboration of toxins in the latter will tend to call forth the elaboration of digestive bodies in her; but if the embryo be not infected then immunity will not be conferred, for in such a case no toxins from the child will call forth the digestive bodies from the mother, and these, as we have seen, do not persist in the body in the absence of appropriate stimulation—i.e., in the absence of toxins—but after a space disappear, leaving behind only the power of tolerating the toxins, only the power of readily producing digestive bodies when stimulated by the toxins.

[11] Be it remembered that here I write in general terms only. As is well known, living children may be born to a woman in all stages of her disease, but abortions and miscarriages are most frequent during the earlier stages, and of such children as are born alive the vast majority perish. It is very significant, moreover, that hand-fed syphilitic children are more liable than those who are breast-fed to marasmus (Coutts). It is known that "antitoxins" are secreted in the milk and other secretions, and Ehrlich actually believes that the hereditary transmission of acquired immunity is due to the presence of large amounts of antitoxins in the milk.

[12] I cannot set forth positive evidence proving that the children born of a mother recovered from syphilis and immune to it are not themselves immune, for I am not aware that any observations bearing on the subject have been published. Nevertheless, reasoning from the analogy of other diseases, we may be sure that they are so, for it is a matter of common knowledge that the children of mothers recovered from and immune to pertussis, measles, scarlet fever, small-pox, typhoid fever, typhus fever, &c., are not immune; on the other hand, the children of mothers who during the pregnancy have suffered from small-pox have been found to be immune; and Chauveau claims to have proved that the offspring of sheep suffering from anthrax have, under similar circumstances, exhibited immunity against that disease. I myself hope soon to publish some observations proving that if a mother be vaccinated during the later months of pregnancy immunity against varicella, and therefore against variola, is thereby conferred on her infant. If I am right as to this—and I cannot doubt that I am—the matter may be of some practical importance, since a single vaccination would then protect two individuals, since a strong healthy woman is better fitted to undergo the illness than a delicate young infant, and since many mothers would prefer to take their child's trouble on their own shoulders. The usefulness of such vaccination would, however, be limited, since it would be available in most instances for one pregnancy only, and in many cases not even for that. I should like to add that I would be extremely grateful to any readers if they would, as opportunity offered, perform this experiment and let me know the result.

LITHOLAPAXY IN THE CIVIL HOSPITAL, HYDERABAD, SIND.

BY RICHARD BAKER, M.A., M.D. DUB., SURGEON-MAJOR, I.M.S.;
LATE ACTING CIVIL SURGEON, HYDERABAD, SIND.

I SUBMIT herewith a list of 204 further cases of litholapaxy performed by me at Hyderabad, making with the 200 cases published in THE LANCET of Oct. 10th, 1896, a total of 404 cases—385 urethral and 19 perineal—between Feb. 1st, 1896, and Feb. 23rd, 1897. I am well aware that there is nothing very unusual in these figures, large as they may appear to British surgeons, and I publish them, firstly, because I believe that enough is not known at home of the nature and amount of surgical work in India, and, secondly, because I understand that the operation of litholapaxy is, after all that has been said and done, still to a large extent under trial in the mother country. I have purposely given somewhat fuller remarks in the list now published as compared with those made in my former communication, and these leave but little for me to add.

It will be seen that I have comparatively seldom had recourse to Keith's operation, not that my appreciation of its value has in any way lessened, but that, having procured for myself one of Weiss's No. 5 fenestrated lithotrites—Keegan's pattern—I have since then only found one case in which the infantile urethra was too small to admit of the performance of the ordinary operation therewith. In such a case the choice of operation, I take it, will be between suprapubic lithotomy and Keith's operation the stone be at all large, and I believe that when, or as soon as, the latter operation is known it will be the one adopted in most, if not in all, cases of this kind. In the case of a small stone Keith's operation, if performed without a hitch, leaves the urethra after operation practically intact (see remark to Case 401 in the accompanying table). Hence I believe that when either (1) no sufficiently large instrument or (2) no instrument for crushing purposes can be introduced into the bladder Keith's operation is indicated; while at the same time I opine that a surgeon armed with Weiss's No. 5 fenestrated lithotrite, made on Keegan's pattern, will but seldom meet with such an instance among his infantile cases.

The last case in the list, No. 404, is a good instance of what may be done with large instruments in the case of boys where the calculus is large enough and hard enough to render an attempt at crushing with a lithotrite that would pass per urethram one fraught with danger to the patient, the instrument, or both. I have given at the foot of the table the summary of results, &c., on the same lines as

A SECOND SERIES OF LITHOLAPAXY OPERATIONS (204) PERFORMED IN THE CIVIL HOSPITAL, HYDERABAD, SIND.

Number.	Caste.	Sex.	Age.	Date of operation.	Size of lithotrite.	Size of evacuating catheter.	Number of times introduced.	Duration of operation in minutes.	Weight of stone.	Days in hospital.	Result.	Remarks.
				1896.								
201.	Mus.	M.	3	July 13th	8	8	2	15	12 gr.	1	R.	Evacuation delayed by lodgment of fragment in cannula.
202.	Mus.	M.	4	,, 14th	8	8	2	15	1 dr. 20 gr.	1	R.	This calculus should not have necessitated a second introduction of lithotrite.
203.	Mus.	M.	17	,, 14th	12	16	1	15	1 dr. 40 gr.	2	R.	An easy operation; succeeded by priapism, almost continuous for 36 hours.
204.	Mus.	M.	9	,, 15th	8	8	1	11	2 dr.	2	R.	Micturition difficult for 12 hours after operation.
205.	Mus.	M.	48	,, 15th	12	16	1	10	1 dr. 40 gr.	2	R.	—
206.	Mus.	M.	5	,, 15th	8	8	1	9	2 dr.	1	R.	Operation easy and rapid.
207.	Mus.	M.	4	,, 16th	8	8	2	9	40 gr.	1	R.	Ditto.
208.	Mus.	M.	48	,, 16th	16	16	4	82	3 oz. 2 dr.	5	R.	A largish stone in a very emaciated subject. Some cystitis.
209.	Hindu	M.	5	,, 17th	8	8	2	9	1 dr. 50 gr.	2	R.	A single fragment escaped detection, but necessitated second introduction of lithotrite.
210.	Mus.	M.	40	,, 17th	12	16	2	11	3 dr. 30 gr.	2	.	—
211.	Hindu	M.	3	,, 17th	6	8	1	1	10 gr.	1	R.	Soft stone crushed by one turn of lithotrite and evacuated instanter.
212.	Mus.	M.	30	,, 17th	12	16	1	3	1 dr. 30 gr.	1	R.	Operation easy and rapid.
213.	Mus.	M.	3	,, 22nd	6	8	1	7	13 gr.	1	R.	Evacuation at first unsatisfactory.
214.	Mus.	M.	3	,, 23rd	6	8	1	5	13 gr.	1	R.	—
215.	Hindu	M.	4	,, 23rd	6	8	1	6	10 gr.	1	R.	—
216.	Mus.	M.	7	,, 24th	8	12	2	14	1 dr. 50 gr.	1	R.	Evacuation materially hastened by use of larger cannula.
217.	Mus.	M.	32	,, 28th	12	8	2	8	3 dr. 12 gr.	2	R.	—
218.	Mus.	M.	4	,, 30th	6	8	1	6	40 gr.	1	R.	—
219.	Mus.	M.	3	,, 31st	6	8	2	9	36 gr.	2	R.	—
220.	Mus.	M.	5	Aug. 1st	8	8	2	10	1 dr. 6 gr.	2	R.	—
221.	Mus.	M.	5	,, 1st	8	8	1	8	40 gr.	1	R.	
222.	Mus.	M.	48	,, 2nd	12	16	1	10	3 dr. 10 gr.	2	R.	Operations simple and rapid.
223.	Mus.	M.	5	,, 3rd	6	8	2	11	3 dr.	1	R.	
224.	Mus.	M.	4	,, 3rd	6	8	2	8	20 gr.	1	R.	
225.	Mus.	M.	78	,, 3rd	12	16	2	28	7 dr.	4	R.	A very unpromising subject who did well.
226.	Mus.	M.	60	,, 7th	12	16	2	16	1 dr. 30 gr.	3	R.	Slight difficulty in micturition for 24 hours after operation.
227.	Mus.	M.	9	,, 7th	8	8	2	19	1 dr. 40 gr.	2	R.	—
228.	Mus.	M.	8	,, 7th	6	8	1	11	1 dr.	2	R.	—
229.	Mus.	M.	8	,, 7th	6	8	1	5	10 gr.	3	R.	Slight œdema of prepuce.
230.	Mus.	M.	3	,, 8th	6	8	1	6	1 dr. 30 gr.	1	R.	—
231.	Hindu	M.	2½	,, 9th	6	6	1	3	10 gr.	1	R.	—
232.	Mus.	M.	70	,, 9th	12	16	2	15	3 dr. 40 gr.	2	R.	Patient old, but evacuation easy and recovery symptomless.
233.	Mus.	M.	4	,, 10th	8	8	2	9	1 dr.	1	R.	
234.	Mus.	M.	25	,, 10th	12	16	1	5	20 gr.	1	R.	
235.	Mus.	M.	7	,, 10th	8	8	1	3	10 gr.	1	R.	
236.	Hindu	M.	4	,, 12th	6	6	2	9	30 gr.	1	R.	All simple cases.
237.	Hindu	M.	11	,, 12th	8	8	2	8	1 dr. 50 gr.	1	R.	
238.	Mus.	M.	34	,, 13th	12	16	1	14	7 dr. 15 gr.	1	R.	
239.	Mus.	M.	19	,, 13th	12	16	2	16	7 dr. 40 gr.	2	R.	
240.	Hindu	M.	55	,, 13th	12	16	3	30	1 oz. 4 dr.	3	R.	A flabby Hindu subject; slight cystitis.
241.	Mus.	M.	4	,, 14th	6	6	1	1	10 gr.	1	R.	Crushing instantaneous and evacuation immediate.
242.	Mus.	M.	10	,, 14th	8	8	3	23	5 dr. 30 gr.	1	R.	—
243.	Mus.	F.	70	,, 15th	12	16	2	25	3 dr. 10 gr.	2	R.	—
244.	Mus.	M.	3	,, 15th	6	6	1	1	10 gr.	1	R.	Small stone; crushed in one turn and evacuated immediately.
245.	Mus.	M.	35	,, 16th	12	16	2	10	2 dr.	1	R.	Similar to last, larger, but quite soft.
246.	Hindu	M.	4	,, 16th	6	8	2	14	50 gr.	2	R.	A small but rather hard calculus.
247.	Hindu	M.	2½	,, 17th	6	8	1	8	45 gr.	1	R.	Practically the same as No. 244, done on 16th.
248.	Mus.	M.	4	,, 18th	8	8	3	28	2 dr.	2	R.	—
249.	Mus.	M.	30	,, 19th	12	16	2	11	5 dr. 20 gr.	2	R.	—
250.	Mus.	M.	2	,, 19th	4½	6	1	2	10 gr.	1	R.	Another rapid operation, in which a new, small lithotrite was first used.
251.	Hindu	M.	8	,, 19th	8	8	2	14	3 dr. 30 gr.	1	R.	A simple operation of the ordinary type.
252.	Mus.	M.	4	,, 20th	4½	8	1	6	20 gr.	2	R.	Cannula used was unnecessarily large.

PERINEAL LITHOTRITY.

				1896.								
401.	Mus.	M.	2½	July 23rd	4½	6	1	5	10 gr.	1	R.	Fluid injected into the bladder per urethram immediately after operation; returned clear by the same route.
402.	Mus.	M.	3	Sept. 7th	4½	7	2	10	½ dr.	2	R.	—
403.	Mus.	M.	5	,, 10th	4½	7	3	20	1 dr. 5 gr.	9	R.	Operation followed by fever, which subsided, and patient did well.
404.	Mus.	M.	7	Oct. 30th	16	14	3	30	6 dr. 5 gr.	5	R.	Stayed in hospital till fistula closed.

SUMMARY.—Mussulmans, 168; Hindus, 36. Males, 200; females, 4. Ages: under 1 year, 1; 1 to 3 years, 65; 6 to 10 years, 36; 11 to 15 years, 4; 16 to 45 years, 53; 46 to 55 years, 26; 46 to 65 years, 13; over 65 years, 6. Oldest, 78; youngest, 8 months. Lithotrite, average number of times introduced, 1·60. Average duration of operation, 12 minutes 19 seconds. Average weight of stone, 2 dr. 46 gr. (nearly). Average stay in hospital, 1·853 days. Mortality, 0·49 (nearly) per cent.

Digitized by Google

those given in my previous paper. They show some improvement in the averages of number of times the lithotrite was introduced, duration of operation, and stay in hospital in each case; but it will be seen that the average weight of the calculi dealt with is lower in this list, and a large number of cases of small stones in young children come to be dealt with very rapidly after some experience, and this will, of course, show itself in an average statement, somewhat obscuring the fact that large stones, if at all hard, will always take time to crush and evacuate. Thus in Case 208 the removal of a calculus weighing three ounces and two grains took as long as eighty-two minutes from the moment of introducing the lithotrite to that of withdrawing the cannula for the last time, while other very small soft calculi if found and seized at once were pulverised by a single turn of the lithotrite handle and evacuated within a couple of minutes.

Matlock Bath.

NOTES ON A CASE OF APPARENTLY INCURABLE BLINDNESS IN WHICH SIGHT WAS RESTORED.

BY CHARLES BELL TAYLOR, M.D., F.R.C.S. EDIN.,
SURGEON TO THE NOTTINGHAM AND MIDLAND EYE INFIRMARY.

THE patient, a girl, twenty-two years of age, who was presented to the notice of the president and members of the Nottingham Medico-Chirurgical Society, on March 25th, 1897, came under my care in September, 1896. At that time she was quite blind, having bare perception of light with either eye. She had been in this condition for upwards of three years, during which period several ophthalmic surgeons had been consulted, with the result that she was declared incurable, and advised to enter an asylum for the blind without delay. "Is it any use going elsewhere for advice," she asked. "Not a bit! no one can do you any good!" Under these circumstances I told the friends that it would be hardly worth their while to incur the expense of a railway journey; but as an uncle of hers—formerly blind from detached retina, and who had been sent to me by Dr. Metcalf, of Lancaster—had regained his sight, they were very persistent, and I consented to receive her as an Eye Infirmary patient. On admission I found both pupils contracted, adherent to the capsule of the lens, and blocked by dense calcareous masses, while the eyes themselves were

Cataracta complicata accreta.

so shrunken and soft that minus three according to Sir W. Bowman's formula was barely sufficient to express their condition. I concluded that the opacity and calcareous degeneration of the lens—cataracta complicata accreta—was a secondary phenomenon; that sight was probably lost before the pupils were blocked; that there had been impairment of the circulation in the vessels of the uveal tract, liquefaction of the vitreous, and possibly also detachment of the retina in both eyes[1]—a diagnosis which was to some extent borne out by notes of the case which were kindly sent to me by Mr. Bickerton, of Liverpool, from which it appeared that she had originally suffered from cyclitis preceded by choroidal changes and complicated with facial paralysis. She had been for some time an in-patient in the ophthalmic wards of a general hospital before coming under Mr. Bickerton's notice, and was subsequently seen and prescribed for by other specialists. I treated her with constitutional remedies *secundum artem*, with the constant galvanic current, and sub-conjunctival injections, and, when the improved condition of the eyeballs and increased perception of light seemed to warrant the procedure, extracted both lenses with the capsule entire and without iridectomy. The operation—despite extensive adhesions and so many contra-indications and drawbacks—was perfectly successful, and she was very soon able to go about the crowded streets—even after nightfall and in the winter months—unaccompanied, to read the signs over the shop windows, and to enjoy a degree of freedom which was highly appreciated after having been led about for years. A continuance of the treatment, after recovery from the operation, was followed by daily improvement, until the death of a relative compelled her return home, since which time I have had letters from her as well written as any I am in the habit of receiving.

"Shall I ever see again?" is a pathetic query which is often addressed to us, and it is one which it is not so easy to answer as might *a priori* be supposed. I have patients who have recovered their sight after blindness of upwards of thirty years—even loss of perception of light is not always a contra-indication to treatment. Indeed, I have one patient from the Blind Asylum who recovered excellent sight by treatment alone, both for reading and distance, after prolonged loss of all perception of light; and it is quite certain that now and again apparently hopeless cases—such as the one I have recorded—may be restored to all the blessings attendant upon the exercise of that function without which life itself is worth little.

Nottingham.

[1] "Inflammation of the anterior portion of the uveal tract, and especially the ciliary processes—in other words, cyclitis, or degeneration of the vessels of the uveal tract—leads to impairment of the nutrient supply of the vitreous and altered consistency, liquefaction or synchisis, and the retina, losing the support of the vitreous, is apt to become detached."—Leber and Nordensen.

CONGENITAL LARYNGEAL OBSTRUCTION.

BY G. A. SUTHERLAND, M.D. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, PADDINGTON-GREEN CHILDREN'S HOSPITAL, AND TO THE NORTH LONDON HOSPITAL FOR CONSUMPTION;
AND
H. LAMBERT LACK, M.D. LOND., F.R.C.S. ENG.,
SURGEON TO THE EAR AND THROAT DEPARTMENT, PADDINGTON-GREEN CHILDREN'S HOSPITAL, AND ASSISTANT PHYSICIAN TO THE HOSPITAL FOR DISEASES OF THE THROAT, GOLDEN-SQUARE.

THIS affection may be described as a form of persistent laryngeal obstruction commencing at, or soon after, birth and accompanied by a peculiar stridor. The affection is not very rare, but is probably often unrecognised, and there are but few references to it in medical literature. Dr. Lees has described a case as a peculiar form of obstructed respiration. Dr. Gee discusses some cases under the heading of "Respiratory Croaking in Babies," and the same affection is evidently referred to by Dr. Goodhart as "infantile laryngeal spasm," by Dr. Löri, of Pesth, as "clonic spasm of the glottis," and by Dr. Robertson as "postical paralysis." Dr. Thomson, of Edinburgh, has written an admirable and full paper on the subject under the title of "Infantile Respiratory Spasm." Within recent years a few cases under various designations have been shown at medical societies, but so far as we are aware no contribution has appeared tending to the further elucidation of the subject. The pathology of the affection has never yet been definitely determined, and the importance of some of its symptoms is not fully recognised. We propose to give an account of the clinical signs and symptoms founded upon the observation of eighteen well-marked cases, to trace the progress of the patients, and to describe exactly the pathological condition of the larynx, which we believe to be the basis of the affection. For the notes of two of the cases we are indebted to our colleague, Dr. Leonard Guthrie.

Predisposing circumstances.—This subject formed part of our investigation, but we have not succeeded in eliciting any facts of importance. Inquiry has been made as to any hereditary tendency to this affection, or hereditary disease associated with it, as to whether any localities are specially

Digitized by Google

affected, and as to whether accidents during pregnancy were common, in all cases with a negative result. In no case had more than one member of the same family been affected. The firstborn did not appear to be more liable than the subsequent children. There was no evidence of the affection being in any way traceable to the nature of the confinement.

CLINICAL FEATURES.

1. *Date of onset.*—The stridor is usually observed at, or very soon after, birth. Its onset may be delayed until the end of the second week, but after that time its occurrence is rare. Of these 18 cases the stridor was noticed on the first day in 11, on the second day in 1, on the third day in 1, on the fourth day in 1, on the seventh day in 1, on the fourteenth day in 1, and in the third week in 2. It is probable that those cases in which nothing abnormal was observed until after the first week had a slight stridor at an earlier period, which might easily be regarded as the normal crowing of infancy, until its persistence and increase during the first weeks of life attracted more special attention.

2. *General health.*—As a rule medical advice regarding the infant was sought solely on account of the stridor. Many of the patients were well nourished and apparently in the best of health, and did not appear to be at all inconvenienced by the laryngeal obstruction. As regards associated illnesses, nothing definite or constant has been noted. Syphilis was probably present in one case, but not to a marked degree. In one case there was a history of convulsions, commencing on the eighth day and recurring at intervals until the end of the second month. A moderate amount of rickets was observed several times amongst the infants over three months of age, but not more frequently than is usual amongst hospital patients. Finally, anæmia was present in one patient, another suffered from marked constipation, and several were specially subject to bronchitis.

3. *Character of the stridor.* — Amongst the various descriptive terms applied by the mothers to the stridor there occur the following: "Like a hen," "like a chicken," "like a grunter," "purring like a kitten," and "like croup." Dr. Thomson says: "Inspiration begins with a croaking noise and ends in a high-pitched note; expiration is accompanied by a short croak when the stridor is loud, but at other times it is noiseless." This is a good description of a typical case, but many modifications and variations occur. Inspiratory stridor was always very much louder than expiratory. The variations in the pitch of the inspiratory stridor were striking, the note in some cases being deep, purring, growling, and in others high, clear, squeaking. The expiratory sound was sometimes of a nasal or pharyngeal character. The loudness of the stridor varied at times, and in almost all of the cases there were periods of complete intermission. The influences bearing on these alterations would appear to be as follows. When the breathing was regular and superficial the stridor was diminished or absent. This was observed usually when the child was asleep or was taken from a cold to a warmer atmosphere. When the breathing was irregular or deepened, the stridor was increased. This was observed when the child awoke from sleep, or was taken from a warm to a colder atmosphere, or was put in a cold bath, or was excited, or frightened, or crying, or coughing, or was being fed too quickly, or when dyspnœa was present, as in bronchitis. The cry and cough were always clear and natural, apart from intercurrent disease affecting the larynx.

4. *Signs of obstruction.*—1. Cyanosis may be, and in many of our cases was, entirely absent. Inquiry elicited the fact that eight of the patients had suffered from suffocative attacks, coming on sometimes when the infant was asleep and sometimes when awake, and accompanied by cyanosis and marked stridor. A condition of persistent cyanosis is very rare, but it was a prominent feature in the only fatal case we have met with. 2. Movement of the alæ nasi was not a marked sign, but there was usually some increase in movement when the respirations were deep and the stridor loud. Dr. Thomson noted the absence of this symptom in his cases. 3. Thoracic and abdominal retraction was present in all except the slightest forms of the affection, but, like the stridor, it was intermittent and varied in degree. The retraction may be visible at the episternal notch, at the supra-clavicular fossæ, along the ribs, more especially in the axillary region, and at the epigastrium. When the stridor was pronounced and had lasted for some months the boundaries of the chest became altered as in rickets. In several of the cases epigastric depression with laboured action of the abdominal muscles was a prominent feature. Even when the stridor was temporarily absent retraction was usually present, although to a less extent than when the breathing was noisy. 4. As a rule the lungs are not fully expanded, the breath sounds being feeble towards the bases, and râles or rhonchi being audible over those areas.

5. *Examination of the nose and pharynx* —In none of the cases examined did we find the tonsils much enlarged or adenoid vegetations of any importance, and in none were there any of the symptoms usually associated with these affections. Our experience in this respect agrees with that of Dr. McBride, who examined some of Dr. Thomson's cases, and is at direct variance with that of Dr. Eustace Smith and Dr. Robertson, who apparently consider the presence of adenoid growths an important etiological factor in the affection.

6. *Examination of the larynx.*—After many attempts, most of which were unsuccessful, the following simple method was discovered, by means of which the larynx of the youngest infant could be quite readily and certainly seen without causing it any pain or inconvenience, and without the necessity of having recourse to anæsthetics. The infant being held in the usual position for laryngoscopy, the index finger of the left hand is passed into the mouth over the base of the tongue and the terminal phalanx hooked round the hyoid bone, which is by this means pressed well forward. The rest of the finger holds down the tongue out of the way, and, with the left thumb pressed up under the chin, serves to steady the infant's head. A small laryngeal mirror is now introduced in the usual way and the larynx comes readily into view. When the child was a little older and possessed teeth a copper spatula suitably bent with a small sharp curve at its end was used in place of the finger, and this instrument is also useful when the examiner's finger takes up too much room in the infant's mouth. The infant as a rule keeps the mouth wide open during the examination, but a gag might be necessary in some cases. This method was demonstrated at the meeting of the Laryngological Society of London in February, 1897. By this means the larynx was examined in six cases—all those seen in the last year—and in all of them the following characteristic appearances were found. The epiglottis was sharply folded on itself, the two lateral folds being in close apposition and in some cases in contact. The aryteno-epiglottic folds were approximated, and thus the upper aperture of the larynx was reduced to a long narrow slit. The thin folds bounding this aperture seemed quite flaccid and flapped to and fro on respiration. The inspiratory column of air striking down on these folds drove them together, and on expiration they again separated. In some cases, the "purring" ones, the coarse vibrations of these folds could be distinctly seen. In only a few of the cases could a view of the vocal cords be obtained. They appeared quite white and normal, as the symptoms would have led one to expect.

7. *Progress.*—In the case of a child otherwise healthy the stridor tended to increase in loudness for some weeks or months after birth, then to continue more or less stationary until the eighth or ninth month, and then gradually to diminish until it was lost about the end of the eighteenth month or second year. After that period it was occasionally represented by a short crow or croak under excitement or any action causing long-drawn inspirations. One patient was seen for the first time when ten weeks old and presented a typical stridor, loud and persistent. This condition continued with little alteration until the twelfth month, when the stridor began to be less loud and less frequent, until at the end of the second year it was observed only when the child was "out of breath," or had a cold, or was straining at stool. When last seen, at the age of six years, she was in robust health, the lungs and heart were normal, and the chest showed no signs of deformity. On laryngoscopic examination the epiglottis was seen to be folded laterally on itself and the aryteno-epiglottic folds approximated. These folds closed inwards when the child drew a hurried breath, and a slight stridor was produced. The vocal cords moved freely. Other cases have been observed up to the ages of from two to two and a half years, and the progress has been similar to that above described, the stridor reappearing only under exceptional circumstances and the malformation of the larynx above described persisting.

PATHOLOGY.

Many divergent opinions have been expressed as to the cause of the obstruction. Dr. Lees has described the larynx

Digitized by Google

in one case which proved fatal from diphtheria. He found the epiglottis folded on itself and the aryteno-epiglottic folds in contact, the upper aperture of the larynx being reduced to a narrow slit with two minute openings, one between the folds of the epiglottis and the other between the arytenoid bodies. Dr. Gee thought the stridor was produced in the pharynx. Dr. Löri, of Pesth, in a series of cases observed a constantly recurring clonic spasm of the vocal cords. Dr. Robertson believed the affection to be posticus paralysis, due to a reflex disturbance of the nervous mechanism of the larynx set up by the presence of post-nasal adenoid growths. Dr. Eustace Smith has accepted this hypothesis and refers to cases of his own in support of it. Dr. Goodhart accepts Dr. Lees' observations, although he had previously thought that the affection depended upon a valvular action of the upper aperture of the larynx due to the flaccidity of these structures in infants. Dr. Thomson advances ingenious arguments in favour of its being a respiratory spasm, the muscles of respiration being imperfectly coördinated. He considers it to be a developmental neurosis and analogous to stammering. Dr. McBride and others who took part in the discussion on Dr. Thomson's paper also considered the affection to be a glottic spasm. From our own observations we are convinced that the affection depends on a valvular action of the upper aperture of the larynx, a falling inwards of its lateral walls during inspiration, dependent partly on a peculiar congenital malformation of the larynx and partly on the flaccidity of these parts in infants. The larynx described by Dr. Lees presents this deformity in a very marked and probably very rare degree. In all our cases a similar malformation was present, but without the associated valvular action of the laryngeal aperture it would not have been sufficient to produce obstruction. Further, we have shown that as the child grows the malformation remains, but the stridor passes off as the parts forming the superior laryngeal aperture become less yielding. The fact that the folds are wider apart at the commencement of inspiration and close during its course agrees well with the observation that the stridor becomes higher pitched at the end of inspiration—that is, when the chink is at its smallest. The flapping outwards also accounts for the diminution or absence of the stridor on expiration. The above described malformation of the larynx has persisted in our cases as long as they were under observation, in one case up to the age of six years, and it is met with occasionally in advanced life, although we have no knowledge if such cases suffered from stridor in infancy. This observation contradicts the objection which some might urge that the laryngeal condition above described was really the normal infantile type of larynx. Besides, one of us has systematically examined the larynx of every infant coming under his care during many months past and has never yet observed the malformation except in association with this affection.

It cannot be definitely decided that the vocal cords play no part in the affection—that there is not, in fact, in some cases bilateral abductor paralysis. But the above condition appears to us to account quite satisfactorily for all the observed phenomena without assuming the existence of an additional lesion. Further, in some of the older patients in whom the upper aperture of the larynx was larger the cords moved well and were seen to be fully abducted, yet in these cases also stridor occurred on exertion or during a quick inspiration, and was invariably associated with a falling inwards of the aryteno-epiglottic folds. The theory that the affection is in any way a spasm seems to us to be untenable in view of the appearances observed, nor does this theory satisfactorily explain the fact that in some cases the obstruction may persist constantly for months, and even during sleep, chloroform anæsthesia, &c.

DIAGNOSIS.

The affection is readily recognised by all who have once seen or heard it. The chief points to be attended to are the early onset, the peculiar characters of the stridor which occurs all day and even at night, with but short intervals of quiet breathing, the evidences of obstructed respiration—retraction of chest walls, &c.—without as a rule any apparent distress, and the loud, clear cry. In addition, we believe the above-described laryngoscopic appearances to be absolutely characteristic. Attention to the above points will be found sufficient to differentiate this affection from the following conditions which may more or less resemble it—(1) laryngismus stridulus and other forms of glottic spasm occasionally met with in connexion with post-nasal growths, excessive crying, &c.; (2) laryngitis in infants; and (3) papillomata of the larynx.

PROGNOSIS.

The prognosis is favourable provided that the infant's general health is good and the amount of laryngeal obstruction is moderate. In the case of infants who are delicate the obstruction to the breathing will probably be an additional factor in retarding the normal growth and development, and will predispose to pulmonary affections from imperfect expansion of the lungs. An attack of acute illness affecting the respiratory passages, such as bronchitis or pneumonia or diphtheria, is more serious in the case of an infant thus affected than in ordinary cases. The possibility that the obstruction to the breathing may lead directly to death from suffocation must be kept in mind. The occurrence is probably a rare one, as we are not aware of any example of this which has been recorded and have only met with one case in our own experience. This was one of our earlier cases and occurred before we had recognised the nature of the pathology and the gravity of the affection. The patient was an infant, aged two weeks, who had been observed to breathe noisily since birth. The stridor had been increasing, and at times the child got black in the face. There was a well-marked persistent stridor, accompanied by slight blueness of the extremities, retraction of the lower costal region, and strong action of the abdominal muscles. A week later the condition was not much altered, but the signs of obstruction were more marked, the cyanosis having increased in the face and extremities. The child died at home the same night, the breathing getting gradually more laboured, the cyanosis deepening, and convulsions supervening half an hour before death. A necropsy, limited to the chest and abdomen, was made on the following day. The external appearances were those of a healthy, well-nourished infant. The heart and lungs were healthy. The thyroid and thymus glands appeared to be normal. The epiglottis was soft and curved inwards. On examination of the larynx, both macroscopic and microscopic, no structural change was detected. The abdominal organs appeared to be healthy. In another patient the stridor persisted unchanged until the age of twelve months, when bronchitis supervened, the child lost flesh, and died eight months later from pulmonary disease. A third case which terminated fatally was that of an infant presenting, at the age of seven weeks, a well-marked stridor, but only slight evidence of obstruction as manifested by costal retraction. At the age of nine months the stridor was distinctly less, but the child was rachitic and suffered from chronic bronchitis. When she was thirteen months old the stridor had almost disappeared, but she died six months later from pulmonary tuberculosis.

TREATMENT.

In the treatment of our earlier cases various drugs were employed with the view of testing some of the current theories as to the nature of the affection. Among these may be mentioned bromide of potassium and strychnia, which were given for considerable periods without producing any definite benefit. In the later cases our treatment has been based on the belief that the affection is really due to a mechanical obstruction to the breathing, and has therefore been directed to the maintenance of as sound a condition of general health as possible. Cod-liver oil and malt, careful dieting, and attention to the general hygiene represent the chief measures employed. It is important that care should be taken to avoid cold, and that catarrh arising in any part of the respiratory tract should be checked as soon as possible, as any additional obstruction to the breathing is serious. For this reason, also, rickets, if present, must be energetically treated. In cases accompanied by cyanosis or severe suffocative attacks the danger of fatal obstruction must be remembered and tracheotomy performed, or the patient placed in circumstances where it can be performed at once if necessary.

THE MECHANISM OF DEATH FROM CHLOROFORM.

BY ALEXANDER WILSON, F.R.C.S. ENG.,

SENIOR ADMINISTRATOR OF ANÆSTHETICS, ROYAL INFIRMARY, MANCHESTER, AND THE VICTORIA DENTAL HOSPITAL, SURGEON TO THE MANCHESTER AND SALFORD LOCK HOSPITAL, ETC.

IN 1893 I described in a communication to the Society of Anæsthetists three cases of death from chloroform[1] in which the prominent symptom was vigorous respiration persisting after the pulse had become imperceptible. Comparing the symptoms in these cases with similar ones occurring respectively in death from sudden hæmorrhage, cardiac syncope, and peritonitis, I suggested the conclusion that these chloroform fatalities were due to anæmia of the respiratory centre produced by "failure of the circulation" from either vaso-motor paralysis or cardiac syncope, and not by primary paralysis of the respiratory centre. I used the term "failure of the circulation" as it did not commit me to any definite theory, my chief object at that time being to prove that death was not caused by primary respiratory paralysis. Since then I have met with three similar cases—one, happily, non-fatal—in my own practice, and with two fatal cases related to me by friends. This class of case is important because the significance of the symptoms is not sufficiently appreciated, and signs which are really of grave import are sometimes taken for signs of safety. The indications of danger to which I wish to draw attention are the same as the classical symptoms of death from hæmorrhage, but the latter are more or less masked by the action of the anæsthetic, and are caused in chloroform fatalities by some serious "failure of the circulation" causing sudden anæmia of the vital centres in the medulla.

CASE 1.—The patient was a boy, aged fourteen years, suffering from a simple cystic enlargement of the antrum. Chloroform was given on lint, and at the beginning of the administration the skin was warm, of a healthy rosy colour, and the pulse good. The anæsthetic was taken quietly; when the patient was "under" the mouth was gagged, the head raised rather suddenly on to a high pillow, and a gouge was thrust into the antrum. At this moment the respiration suddenly became more rapid and deeper, of a character expressing extreme "air hunger"; the pupils dilated widely, the pulse became very feeble and almost imperceptible, and the skin changed from a rosy hue to dead pale. I at once lowered the head and began to compress the chest vigorously; by this time the respirations had become very slow. The dependent position of the head and vigorous compression of the chest soon restored the circulation, normal respiration, and colour, but not before the patient had been in extreme peril. The signs of danger were the increased frequency of the respirations, associated with sudden wide dilation of the pupils, very feeble, running pulse, and pallor of the skin. The pallor of the skin of the face was not so marked as that of the body. This was due, I think, to the manipulation of the face involved in the putting in of the gag, cheek retractor, &c., causing a local hyperæmia of the lips and cheeks.

Regarding the cases related to me the information is not so complete.

CASE 2.—A boy, aged fifteen years, had been anæsthetised with chloroform for the removal of post-nasal adenoids. The operation had been completed and the anæsthetic withdrawn, when the patient was noticed to be breathing deeply. The operator observed some peculiarity about the colour of the face, but was reassured by the presence of free respiration. The respirations, however, suddenly ceased, and all efforts to resuscitate the patient failed.

CASE 3.—In this case a child had chloroform given for a slight operation. When the incision was made there was no hæmorrhage. This drew attention to the pulse; respiration, which had been observed throughout the administration, was then going on freely, but the pulse was imperceptible. Respiration soon ceased and a fatal result ensued.

The first case demonstrates the advantage of the line of treatment adopted, and the other two illustrate how easily the signs of danger may be overlooked. The indications for treatment are to get blood to the respiratory centre, to stimulate the heart, and to restore the blood pressure. For this purpose intermittent compression of the chest such as is obtained in artificial respiration is most valuable. It is not enough to get air in and out of the lungs by inflation or faradaisation of the phrenic nerves; the chest must be compressed so that some pressure is brought to bear on the heart. In the case of a rigid chest-wall I have seen benefit from pressure on the epigastrium directed so as to press in the direction of the heart. The value of compression as a stimulant to a failing heart seems well illustrated by the two following cases.

CASE 4.—I once delivered a woman of an apparently healthy, well-formed child, who, in spite of vigorous respiratory efforts, was unable to get air into the chest, and soon died. The difficulty arose from congenital absence of the diaphragm. The point of interest is that the heart continued to beat for some time, and whenever it had apparently ceased pressure over it re-started vigorous pulsations.

CASE 5.—In another instance, a man in a state of collapse, with badly fractured ribs and other injuries, was temporarily improved as regards his pulse by intermittent pressure over the heart, which from the falling in of the ribs could be exerted to great advantage.

In addition to stimulating the heart, artificial respiration, as pointed out in the Report of the Hyderabad Chloroform Commission, is remarkably successful in restoring the blood pressure—so much so, that "when the animal was really dead it was found in some cases that artificial respiration still maintained a small mean pressure in the manometer," and I have seen at least one instance, in the case of a child, in which, judging from the ruddy complexion and colour of the lips, the colour of which actually returned after pressure, a certain amount of blood pressure was kept up by artificial respiration when the patient was dead. The artificial respiration being employed to treat the dangerous failure of the circulation, not merely to get air into the lungs, it should be resorted to at once, before waiting for the cessation of the deep respirations, therefore to delay treatment until the respirations cease is to wait until the vital centres have been damaged beyond recovery and to lose the patient. I believe the value of artificial respiration in the treatment of chloroform accidents lies very largely, if not solely, in its action as a mechanical cardiac stimulant and restorer of the blood pressure, and to be effectual it must be performed so as to compress the chest.

If the above theory as to the cause of death is correct, we have in it an explanation of the mechanism of certain anomalous forms of death from chloroform. I refer to that class in which spasmodic contractions of some or all of the muscles are a prominent feature, the affection of the muscles varying from mere spasm of the jaw muscles, trismus, with fixation of the chest, to general convulsions resembling epilepsy. There are a large number of these cases reported in the medical journals, and I am not aware that any satisfactory theory has been advanced for their explanation. In 1859 Kussmaul and Tenner[2] showed that the convulsions produced by hæmorrhage were due to interference with the nutrition of the motor centres behind the optic thalamus, consequent on the deprivation of blood, whether this deprivation or anæmia was brought about by hæmorrhage or by ligation of the vessels supplying the brain, and a similar sequence of symptoms is apparently produced by drugs which cause sudden paralysis of the circulation—e.g., hydrocyanic acid. The chief symptoms of anæmia of the basal centres, as exhibited in rabbits, are transient contractions of various sphincter muscles of the face, followed by their relaxation, acceleration of the respiration, dilatation of the pupils, extremely violent general convulsions, clenching or alternate opening and shutting of the jaws, and occasionally voiding of urine and fæces. The general convulsions are followed by a period of quiet, in which there are at intervals deep sighing respirations, during which the chest expands enormously and the heart beats vigorously, but the pulse is imperceptible.

An almost identical series of phenomena occurs in death from sudden hæmorrhage or sudden "failure of the circulation" from any cause in man, and the same symptoms, having their origin in a similar cause, are seen in certain deaths from chloroform; but, naturally, they are to a greater or less extent obscured by the degree of general narcosis, and upon

[1] THE LANCET, Nov. 17th, 1894, p. 1148.

Digitized by Google

this depends the various and at first sight conflicting conditions under which death from chloroform presents itself. The anæmia of the respiratory and other centres, which, in a conscious man or animal will produce general convulsions, will in the same being, were he anæsthetised, cause symptoms affecting only the series of muscles not under the influence of the anæsthetic. In accordance with the Law of Dissolution, a general anæsthetic like chloroform should affect the various nervous and muscular system of the body in a certain progressive order, the various portions of the accessory system becoming narcotised first, and the more fundamental systems being affected last. Something like this does happen, for of the various voluntary muscles and muscular systems of the body the jaw muscles and certain facial muscles are affected late, and the respiratory muscles last of all. A patient may be sufficiently unconscious for the performance of a surgical operation, while a number of muscles and organs are unaffected and capable of responding to their natural stimuli. Further, when death does happen under chloroform it is not, as a rule, due to the regular progressive narcotic action of the drug, as in the case of opium poisoning, but it arises from the sudden excessive action of the agent on some vital centre or the paralysis of one centre secondarily to the weakening or death of another. This is proved by the fact that death may and does happen at any stage of the anæsthesia, and the symptoms of death vary according to the stage of anæsthesia. I consider that this death is always from "failure of the circulation," and that the widely divergent symptoms attending dissolution depend upon the degree of narcosis present when the failure of the circulation has reached a point incompatible with the proper nutrition of the vital centres.

The signs of danger have to be taken from the organs which are left intact to give them. Thus, if the failure of circulation takes place at a very early stage, before the general muscular system is narcotised, it will be indicated by accelerated respirations, dilated pupils, and general convulsions resembling epilepsy, the symptoms terminating with deep gasping respirations, ceasing suddenly, as in the following fatal case.[3]

CASE 6.—The patient was a man, aged thirty years, described as not in "robust health." Chloroform was given to him while he was "sitting in a chair," a position conducive to cerebral anæmia; he appeared to be going off comfortably when he began to raise his hands and kept spitting on the lint, and appeared as if about to vomit. Suddenly he was violently convulsed through his whole frame, as if in an epileptic fit. The administration of chloroform was discontinued and he was laid in a semi-horizontal position. The convulsion only lasted for a few seconds, and when it ceased he began to breathe with effort and puffing of the lips, and immediately to gasp irregularly. His pulse was almost imperceptible and intermittent.

If the degree of narcosis is still deeper when the failure of circulation takes place, the anæsthetised muscular system will not respond as a whole, there will be no general convulsions, but only spasm and disordered action of the less narcotised muscles, such as clenching of the jaws and rigidity of the chest muscles, as in the following case, also quoted from Snow.[4]

CASE 7.—The patient, a man aged forty-three years, struggled a good deal. In a short time the inhalation took effect and he began to snore; the chloroform was then removed. The incision was just about to be made when it was noticed that the pulse, previously good, "was gone." At this stage the face was much congested, the jaws were firmly closed, and the pupils dilated. Artificial respiration was begun; in a few minutes he made a long inspiration. This was soon followed by a second, by a third at a longer interval, and at still longer periods by a fourth and a fifth, when all attempts at natural breathing finally ceased. The chest was noticed to be much contracted, to have apparently lost its elasticity, and not to expand when the ribs were forcibly compressed during the artificial respiration—i.e., it remained fixed in a condition of expiration, a state which has frequently been observed.

Failure occurring at the stage of ordinary surgical anæsthesia, when with the exception of the respiratory system all the muscles are relaxed, will be denoted by exaggerated respiratory movements and dilated pupils, as in the cases described in my previous paper. When death ensues without any exaggeration of the respirations it may be assumed that the anæsthetic has been gradually absorbed to such an extent as to paralyse the respiratory centre and render it incapable of expressing its condition of anæmia by the normal method of exaggerated respiratory movements. I think the truth of these conclusions will be confirmed by experiments with a drug which causes sudden paralysis of the circulation, such as hydrocyanic acid or some of the nitrites. The symptoms produced by poisonous doses of hydrocyanic acid are almost identical with those already described as induced by sudden hæmorrhage. There is rapid respiration, convulsions, followed by deep sighing respiration, rapid action of the heart, quick feeble pulse, &c., with general vascular dilatation, all being evidence of anæmia of the motor centres behind the optic thalamus, and manifestly caused by the poison paralysing the circulation. In the case of hydrocyanic acid, as the heart continues to beat for some time, the lesion is evidently a vaso-motor paralysis. By the administration of this drug to animals in different stages of chloroform anæsthesia a similar succession of symptoms could no doubt be produced such as are seen in these various forms of death from chloroform in man. This analogy between the symptoms produced by hæmorrhage and those produced by fatal doses of chloroform also throws some light upon the question of idiosyncrasy, and may explain the occurrence of some fatal cases. In the old bleeding days it was well recognised that certain individuals could not bear loss of blood, however slight, without experiencing serious constitutional disturbances, such as fainting, or general convulsions, which meant that the motor centres of those individuals were so unstable that they were intolerant of any change in their blood-supply. Any alteration in the direction of lowered blood pressure in these persons would be equally productive of similar consequences. May it not easily be the case that in such persons the normal and unavoidable disturbances of the circulation following the inhalation of chloroform would be dangerous and productive of fainting or even fatal syncope? It is clear that in these cases death is not due to primary paralysis of the respirations, but to failure of the circulation.

What is this "failure of the circulation" which causes anæmia of the respiratory and other centres? In my previous paper I suggested that it must be due either to vaso-motor or to cardiac paralysis, and I inclined to the former theory. In some notes on the Hyderabad Chloroform Commission[5] I pointed out that, if those carefully performed experiments proved anything at all, they certainly did prove that the chief danger from chloroform was the induction of vaso-motor paralysis. On looking over the report of the Commission at this interval of time it is difficult to imagine how such careful observers could have ignored the evidence in favour of vaso-motor paralysis as the cause of death in nearly all fatal cases. Professor A. W. Hare, in a recent paper, in which he gives his adherence to the theory of vaso-motor paralysis, shows that the one point upon which all laboratory experiments do agree is that the inhalation of chloroform invariably causes a fall in the blood pressure, and the late researches of Dr. Leonard Hill tend to confirm that view. How far the heart contributes to the fatal result, either by its own inherent weakness or from its becoming affected by the anæsthetic, is a problem still awaiting solution. Dr. Alexander Haig[6] has ably advocated the theory that in the rise of blood pressure which follows the cessation of chloroform inhalation the weakened heart becomes overpowered by the high pressure. This may explain a certain number of cases, but does not apply to the majority.

Considering the experimental evidence, the clinical evidence, the light thrown upon the subject by a comparison of the symptoms with those of death from other well-recognised causes, and the effect of treatment, there can be no doubt that in most, if not all, cases death from chloroform is due to vaso-motor paralysis, or at least the fatal changes are initiated by the fall in blood pressure. The symptoms preceding death vary according to the degree of narcosis that has been reached at the time when the vital centres begin to be affected by the depletion of blood consequent upon the vaso-motor paralysis. Under these circumstances it is of importance to know what means are available for estimating the blood pressure in a patient

under chloroform. This is a difficult matter, the heart and pulse being in themselves imperfect guides, for as the pressure falls the heart beats more vigorously in attempting to keep it at the normal standard, and what may at first sight appear a good pulse may be only an extra effort on the part of the heart to restore the falling blood pressure. The pulse in chloroform anæsthesia, as in everything else, requires discrimination for its observation and must be considered in conjunction with other signs. Again, the colour or complexion of the patient is not of much help in itself, as there are many instances in which persons who enjoy perfect health have almost corpse-like complexions, and equally many with feeble circulations, or even the dead, may have a colour, as in the case of the child previously mentioned. Probably the best index of the condition of the blood pressure we possess is the circulation in the capillaries, and the best way of testing this is by pressing on the lips or gums and noting the rapidity with which the blood returns after the compression. The circulation in the capillaries is a matter of blood pressure, if the blood returns rapidly the pressure may be regarded as good, if it returns slowly the pressure is low. Some information can also be obtained from the way in which the blood stagnates in dependent parts, such as the dependent cheek or ear, &c.

There are a number of minor signs worthy of study—e.g., movements of the alæ nasi and facial muscles, alteration in rhythm of the respirations, and the like. All of these indicate some change in the condition of the patient. In one instance, in the case of an old man who, towards the end of an operation, was slightly under the influence of chloroform, the first indication of failing circulation was the occurrence of yawning, which led me to lower the head and take measures to stimulate the circulation. Signs such as these are of more value than the mere rate, volume, &c., of the pulse, as they show to what extent the circulation is being efficiently performed and is really effective, and it is well known under what different conditions of pulse an efficient circulation can be kept up.

Note.—Since the above paper was written and sent off Dr. Leonard Hill has published a valuable communication on the Causation of Chloroform Syncope.[7] The conclusions arrived at by Dr. Hill from experimental evidence are, in the main, in accordance with those expressed in the above paper and obtained from a study of the symptoms observed in cases of chloroform syncope.

Manchester.

A CASE OF DOUBLE VASECTOMY; DEATH; PARTIAL NECROPSY.

BY W. FRANK COLCLOUGH, M.B., B.C. CANTAB.,
MEDICAL OFFICER TO THE BRITISH HOSPITAL, OPORTO.

A MAN, aged seventy years, of unusual physique, commenced to have prostatic trouble at the age of sixty-seven years. He had been a free drinker, especially of whisky, but had always led an exceptionally active out-door life. The irritability of the bladder commenced gradually, with attacks every three or four months. I first saw the patient in October, 1894, when he was suffering from an attack of acute cystitis. Confinement to bed, simple treatment, and washing out the bladder had the desired effect, and eventually, with very careful "catheter life," the patient was able to go fishing all day and could walk from ten to fifteen miles. In October, 1894, the prostate was enlarged (both lobes equally to the finger); there was no definite retention, and a large-sized Jacques catheter passed with ease. For the next fourteen months—i.e., until Christmas, 1895—the patient was very comfortable, putting on flesh, and going about his work. In December, 1895, urethritis commenced, and it was necessary to pass the catheter every six hours. The left lobe of the prostate had apparently increased very considerably, and the patient used to complain of pain in the region of the left kidney; this pain was fixed and of a severe, dull, aching character. From this time the patient gradually became worse and worse. He lost flesh, complained terribly of flatulence and dyspepsia (the pain at times was "crippling"), and the urethritis became almost constant. No urine was passed except by the catheter, and there was frequently pain in the perineum and just above the pubes on the left side. Finally the patient's life became almost unbearable, and in the middle of October, 1896, an attack of acute cystitis occurred, with a temperature of 104° F. Treatment improved this, and then, as the patient was comparatively well, double vasectomy was decided upon, in the hopes of relieving the bladder troubles. Mr. Arthur Shillitoe saw the patient with me in consultation. Examination of the prostate was extremely painful; both lobes were enlarged. On the left side the lobe was apparently the size of a large Tangerine orange. On passing the finger into the rectum a definite groove was felt in the mass on the left side, and it was not possible to pass the finger beyond the upper limit of that mass. A large-sized catheter passed easily, and the urine was clear, containing no albumin.

Operation (Nov. 11th, 1896).—The A.C.E. mixture was given by Mr. Arthur Shillitoe. Examination of the left epididymis showed the presence of chronic enlargement. An incision was made over the right cord at the top of the scrotum, as there was a number of enlarged veins. These were separated from the vas; the latter was drawn quite out of the wound, about three-quarters of an inch excised, and the two ends were tied securely with catgut. The wound was dusted with loretin, the edges were brought carefully together and sutured with fishing gut, loretin and boracic acid dusted over, and a sealed dressing of sal alembroth gauze and collodion was applied. The left side was treated in the same way. The patient took the anæsthetic badly, and when "coming to" became wildly delirious, tearing his bandages off, and everything had to be re-dressed. A catheter was passed at 3 P.M., at 7 P.M., and at 10 P.M. During the night the patient passed urine naturally, but with a little pain, every hour. For about six months previous he had never been able to pass urine naturally. On the 12th the temperature was 99° and everything was quite satisfactory. Ten grains of boric acid three times a day were ordered. On the 13th the patient had a good night. He passed urine naturally twelve times in twelve hours with less pain, the quantity passed being three pints and eighteen ounces. The catheter was passed twice. On the 14th the temperature was 99°. The urine contained pus. It was passed freely and naturally and with less pain to the quantity of three pints and six ounces, and was retained once for three hours and twenty minutes. The patient was ordered to sit up in bed. On the morning of the 15th the wounds were dressed. There was primary union. The urine contained a quantity of pus and the patient had diarrhœa. He was ordered to sit up in a chair. In the evening, during the nurse's temporary absence, the patient got up and walked to the closet, which was outside at the end of the balcony, a cold east wind blowing. Here he remained for some time, the result being blood in the urine, a large quantity of pus, and refusal to take food. The bladder was washed out. On the 16th in the morning the patient was flushed, and he complained of flatulence. He had passed a pint and seventeen ounces of urine naturally in twenty-four hours. The bladder was washed out, and two grains of β-naphthol and five grains of bismuth salicylate three times a day were ordered. In the evening the patient was better and the urine clearing. The bladder was washed out. For the first time there was some difficulty in passing the catheter. The temperature was 98°. On the morning of the 17th the patient was better. The temperature was 98·4°. There was difficulty in passing the catheter. The urine was foul but acid. He had passed urine freely and naturally during the night (three pints and four ounces), but owing to the difficulty and pain when the catheter was passed the patient would not permit it to be done during twelve hours. In the evening he was better, and the urine was free from pus. He did not take food well. On the 18th the temperature was 98·6°. A catheter was passed. The bladder was washed out; the residual urine, six ounces, was foul-smelling but acid. The incisions were dressed; the left had quite healed, but the right was rather irritated, and so was the scrotum. The patient had passed three pints and five ounces of urine naturally. On the 19th (the eighth day after the operation) the prostate was examined; the right lobe was about half the size it was before the operation; the left lobe below the groove was distinctly softer, but there was no change in size. The urethra measured roughly by the catheter seven inches. A

coudé catheter was passed with some difficulty. The urine was in a better state. The patient had had a good night, but suffered slightly from diarrhœa. The temperature was 99·4°. On the 20th the urine was very foul. The patient's appetite was failing. There was less diarrhœa. About two pints of urine had been passed naturally. The temperature was 99·8°. On the 21st the tongue was dry. The bladder was washed out at 6 A.M. The urine was very foul (? ammoniacal). At 11 A.M. the urine was slightly acid, and not so foul; two pints and one ounce were passed naturally. On the 22nd the patient was better. The temperature was 99·2°. The urine was less foul; the quantity passed naturally in twenty-four hours was about two pints. On the 23rd the patient was better. Two pints and five ounces of urine had been passed. On the 24th a large catheter was used. The patient was given a hip bath. He was walking about the room. On this day the nurse left. The patient was fairly comfortable until Dec. 1st, when an attack of acute cystitis supervened, and as there was so much difficulty and pain on passing the catheter, after a consultation on the 3rd with a Portuguese colleague, Dr. Roberto Frias, it was decided to tie in the catheter. The patient was put on milk diet and the bladder washed out every six hours. For a day or so he improved, but on Dec. 14th he became more or less delirious and died in a comatose condition on the 18th. For about two days before death the patient would lie with his legs drawn up, and he complained of terrible pain when they were touched, although the abdomen was quite supple and there was no pain on pressure. This symptom was accounted for after death.

Necropsy.—It was only possible to have a very slight and hurried post-mortem examination. On opening the abdomen

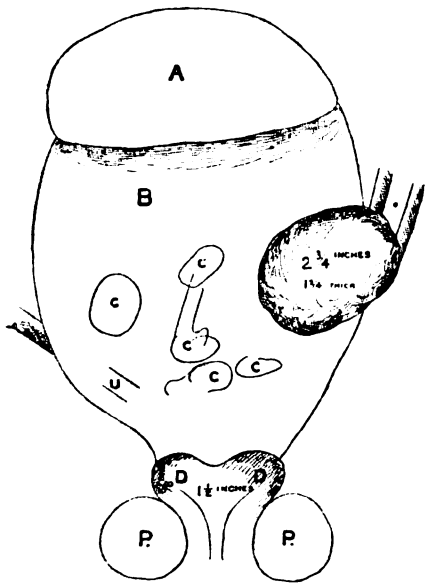

Diagram of bladder laid open by vertical incision viewed from the front. A, The thinned portion of bladder-wall. B, The thickened portion with C, sacculation. U, Opening of right ureter. D, Middle lobe of prostate. P, Lateral lobes of prostate.

the first thing noticeable was that there were several coils of intestine in front of the bladder below, and that the whole of the front surface of the bladder, with the exception of the upper third, was in a state of acute inflammation. The prostate gland was simply a bag of pus, and the bladder itself was anchored down to the posterior wall of the abdomen. The left kidney was with a great deal of difficulty torn away from its surroundings, as it was firmly bound down by recent as well as old adhesions, and to the feel it was simply a bag containing fluid. The left ureter was about the size of one's forefinger. The right kidney was hypertrophied but came away quite easily, and the right ureter was apparently normal. The two kidneys, ureters, and bladder were all taken away for examination. The lower two-thirds of the bladder were very much hypertrophied and thickened; the upper third was just like a bag of parchment. Apparently joining the left ureter was a mass which I at first thought must be malignant growth. On opening the bladder and stretching it out the lateral lobes of the prostate just oozed with pus; the middle lobe was soft and pendulous (suggesting the cause of the difficulty in passing the catheter) and measured an inch and a half from side to side and five-eighths of an inch from above downward. The lower two-thirds of the bladder were sacculated and very much thickened, and there was pus in all the sacculations. The right ureter opened normally, but the left ureter apparently lost itself in the mass of new growth, which was almost circular, measuring two and three-quarter inches in diameter and one and three-quarter inches in thickness (*vide* Figure). Below this mass was a closed-in abscess cavity with thin, smooth walls two and a-half inches in length. The left ureter was very much hypertrophied, about the size of one's forefinger, and lost itself blindly in the mass of inflammatory tissue. The opening could not be found, and it seemed to be quite shut off about two inches from the bladder-wall. There was little or no renal tissue left in the left kidney, which was simply a bag of pus. From the information I gained after death, I should conjecture that the inflammatory growth had been present at least a year, and that probably for many months no urine had passed into the bladder by the left ureter. The condition of old and recent inflammation about the left kidney quite explained the pain the patient had suffered from, as did the condition of the prostate and intestines, the cause of the drawing-up of the legs, although there was no evident peritonitis on the surface of the intestines. Portions of the mass of new growth were sent to the Clinical Research Association. Their report was: "There is no evidence of malignant disease in these portions of bladder. But the muscular coat of the organ is infiltrated with an abundance of dense inflammatory material. There are the indications of fasciculation and sacculation of the bladder, due to the prostatic enlargement. No doubt this induration is due to the chronic cystitis, and by compression of the ureter has caused secondary changes in the kidney."

The clinical evidence of the value of the operation in this case seems to me most satisfactory, for within sixteen hours the patient passed urine naturally. On the eighth day after operation there was definite evidence to the finger that the prostate was not only softer but smaller. I cannot help thinking that the trouble in passing the catheter on the fifth day was due to the middle lobe becoming softer, and therefore acting as a valve, preventing the admission of the catheter, because at times the instrument would pass with the greatest ease. I do not see how the condition of the bladder and left kidney could have been recognised before death, and with my present knowledge my amazement is that the patient lived as long as he did.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THYMOL AS A VERMIFUGE.

BY F. M. SANDWITH, M.D. DURH., M R C.P. LOND,
PHYSICIAN TO KASR-EL-AINI HOSPITAL.

FOR many years I have been using thymol as the most perfect destroyer of the ankylostomum duodenale and any accompanying parasites in the intestines of my Egyptian patients. Sometimes it takes many doses of the drug to rid a man of his last remaining nematode, but the following case ought to encourage any doubters to persevere with the thymol treatment.

A man, aged thirty-three years, was admitted from the out-patients on April 29th, 1897. He was a peasant from Assiout, but for the last two years he had worked in Cairo. He was found to have anæmia from ankylostomiasis of twelve years' duration, and for the last year he had had pellagra. On May 2nd he was given sixty grains of thymol in two doses upon an empty stomach followed by a purge. In the fæces that afternoon were found 523 specimens of ankylostomum duodenale besides 55 oxyurides. On the 7th the thymol treatment was repeated. No ankylostomum duodenale was found, but there were 3 oxyurides. On the 17th the thymol treatment was employed for the third time,

Digitized by Google

but no worms were passed and no eggs were found microscopically. The three examinations in the case of this patient were made by Professor Looss, of Leipzig, thus precluding all error, and it is fair to say that the cause of this chronic disease was removed by sixty grains of thymol. The patient was extremely anæmic on admission, but three weeks later was much less so, owing to the administration of iron, rest, and better food. His weight remained at 138 pounds before and after treatment. The symptoms of pellagra were a slight roughness of skin on the extensor surface of the hands, forearms, elbows, feet, legs, and knees, the tongue pale and denuded of epithelium, and increased knee-jerks. He was sad and melancholy-looking and unable to smile, and there was tenderness on pressure over the spinal nerves on both sides of the fifth dorsal vertebra. Thymol has, of course, no direct effect upon the poison of pellagra.

Cairo.

A CASE OF A FOREIGN BODY TRAVERSING THE ALIMENTARY CANAL.

BY MAURICE EDEN PAUL, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.

A BOY, aged three and a half years, swallowed a copper ring on the evening of June 26th, choking and cyanosis ensuing for a short period after it had left the mouth. When I first saw the child, half an hour later, he was sleeping tranquilly. The symptoms had indicated that the ring was a tight fit in the post-tracheal portion of the œsophagus; but I trusted to the well-known rule that any object of simple shape that passes from the mouth to the stomach is not likely to stick lower down, and my confidence was rewarded by the passage of the ring, embedded in a mass of fæces, on the morning of July 1st. The patient had been entirely free from inconvenience while the foreign body was in his alimentary canal.

It is surprising how readily such objects as this pass through the ileo-colic orifice. The orifice is described by Quain as a slit about half an inch in length; and yet in this case a ring only a shade less than three-quarters of an inch in diameter passed without difficulty in a little child.

Nagasaki, Japan.

SEVERE SYMPTOMS FOLLOWING THE ADMINISTRATION OF A SMALL TEASPOONFUL OF CAMPHORATED OIL.

BY FRANCIS S. TIDCOMBE, L.R.C.P. LOND., M.R.C.S. ENG., L.S.A. LOND.

A MALE child, aged one year and ten months, was given a small teaspoonful of camphorated oil instead of "cough mixture." When the mistake was discovered (some two or three minutes afterwards) the nurse gave the child half a teacupful of cold water with a teaspoonful of salt in it. The child did not vomit or show any symptoms until about twenty minutes later, when he fell on the carpet "in a fit." The fit lasted "a few seconds," and the child remained unconscious. The nurse picked him up and carried him to my house (about two minutes' run). On the way he vomited. When I saw him he was quite unconscious, the extremities were cold, the breathing was deep and slow, there was hardly any pulse at the wrist, the eyes were half closed, and the pupils were widely dilated. I applied hot sponges over the heart and administered a weak current of electricity. He rapidly revived and was again sick. As soon as he could swallow I gave him a copious draught of warm milk-and-water, which speedily returned. Within half an hour he was able to walk. He was sick twice more after drinking milk, and was decidedly drowsy all day. The strength of the camphorated oil was about 1 in 4, so he must have taken about 15 grains of camphor.

Guy and Ferrier describe two cases, in one of which 20 grains caused severe symptoms in an adult, and in the other 30 grains proved fatal in a child aged eighteen months. Considering the very frequent use of camphorated oil as an application to the chests of infants and young children it seems to me that it ought always to be sold in distinctive bottles and labeled "Poison."

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

NORTH LONDON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

A CASE OF "CHRONIC MALIGNANT ENDOCARDITIS"; NECROPSY.

(Under the care of Dr. G. D. PIDCOCK.)

FOR the notes of the case we are indebted to Mr. C. Stanford Read, resident medical officer.

A man, aged thirty-four years, was admitted to the hospital on March 2nd, 1897, under the care of Dr. Pidcock, complaining of weakness and shortness of breath. The patient's past history was as follows (some of the details of it have been kindly supplied by the medical practitioner under whose care he had previously been). He had rheumatic fever when five years of age, and subsequently had been subject to rheumatic pains in various parts necessitating his giving up work for a short time. He nevertheless had fair health till September, 1896, when he had to give up his work on account of progressive weakness, cough, occasional vomiting, pains in the chest, and shivering at times. He had had on two or three occasions attacks of pyrexia of a remittent type. Diarrhœa and vomiting were marked symptoms at times, and this his medical attendant had put down to errors in diet in one who was an invalid. In the course of his illness he had pleurisy (? splenitis), bronchitis, and pneumonia, and always the cardiac trouble, but no œdema at any time. On admission the patient looked very haggard and worn, with a slight malar flush on each cheek. The respiration was 20 per minute; the pulse was 108, of medium size, somewhat irregular in force and rhythm, and of fair compressibility; and the temperature was normal. His lungs seemed to be normal, except for some small crackling *râles* at the extreme right base. On examination of the heart the apex beat was seen and felt in the fifth intercostal space (three-quarters of an inch outside the nipple line), the impulse being markedly heaving. On percussion there was distinct evidence of considerable hypertrophy and dilatation of both sides of the heart. There was a well-marked thrill to be felt all over the cardiac area, the exact timing of which was difficult—at any rate, it was mostly systolic. It was especially marked in the second left intercostal space. On auscultation there was heard a long, loud murmur, which it was also very difficult to time on account of the irregular action of the heart. No second sound was detected at the apex. At the base a distinct to-and-fro murmur was heard, especially loud over the second left costal cartilage, where it had a very superficial character. Further examination revealed the fact that the systolic murmur was audible over the whole of the pulmonary area. The other organs presented no abnormalities. The urine was of specific gravity 1018, acid, and contained no albumin or deposits. For some time the patient made good progress; he felt better generally and put on weight, and the heart's action became much more regular under treatment. Pain in his right side was occasionally complained of. All went well till March 24th, when he complained of diarrhœa and sickness accompanied with some abdominal pain. On the 25th he was sick three times and the bowels were opened five times, the stools consisting mostly of undigested milk. On the 26th he was sick twice and the bowels were opened seven times. The pulse was very soft, but only slightly irregular. On the 27th the bowels were opened seven times, the motions being rather foul. There was great tenderness all over the abdomen. The heart condition was the same, but the thrill was not so marked. On the 28th the sickness stopped. He felt very weak. The bowels were opened four times. He complained of giddiness and not being able to see

Digitized by Google

well. The abdominal pain was not so acute, but the abdomen was still very tender to palpation. There was a slight icteric tinge in the conjunctivæ. On the 29th there had been no more diarrhœa or vomiting. The patient was gradually sinking; his face was somewhat cyanosed, with the icteric tinge more marked. Great abdominal pain occurred till within a quarter of an hour of death.

Necropsy.—At the post-mortem examination the pericardium was found to be normal, and its cavity contained no excess of fluid. The heart was tremendously hypertrophied, but this was most marked on the right side. The pulmonary artery was seen to be enormously dilated. The pulmonary valves were much diseased and quite incompetent, one valve having been quite destroyed and the others being thickly studded with sloughy vegetations. Inside the right ventricle were vegetations and ulceration, just in the position where the valve that had been destroyed might have flapped back and infected the area. The other valves of the heart were healthy, but the mitral and tricuspid orifices were both dilated, especially the former, and it is probable that mitral regurgitation had taken place during life. The lungs were congested, but otherwise normal; no signs of infarcts, recent or old, were found. From the cardia to the rectum there were signs of a most severe gastro-enteritis, fully accounting for the abdominal pain, diarrhœa, and vomiting. The mucous membrane of the stomach was somewhat atrophied. No signs of emboli or ulceration were observed anywhere in the alimentary canal. The liver and spleen were congested, but otherwise they were normal.

Remarks by Dr. PIDCOCK.—This case presents many features of interest. During the patient's stay in the hospital his temperature, taken twice daily, never rose above normal; nor was there during the last two months of his life or on post-mortem examination any evidence of multiple embolism. The absence of both these most typical signs of ulcerative endocarditis is very remarkable. During his illness (commencing in September, 1896) he certainly had pyrexial attacks, rigors, and occasionally coloured sputum and perhaps an attack of splenitis, all of which were doubtless due to embolism. Still, he had not many of the most usual signs or symptoms of infarction, such as hæmaturia, retinal or cerebral hæmorrhage, or blocking of any of the arteries of the limbs, &c. He had an attack of acute rheumatism at five years of age, which may have affected the endocardium of the right ventricle and pulmonary valves, or, what is even more probable, he may have had endocarditis of the right ventricle during fœtal life. Whether this was the case or not, I think there can be little doubt that the endocardium of the right ventricle and pulmonary valves were infected during the attack of pneumonia which he appears to have had in September, 1896. The intensity of the gastro-enteritis from which he succumbed was also very remarkable. From the stomach downwards the mucous membrane was intensely congested. I cannot see how it could have been caused by emboli, and one would hardly expect an error in diet to have been sufficient cause, and yet nothing else could be discovered to account for it.

DERBYSHIRE ROYAL INFIRMARY.

A CASE DIAGNOSED AS ACUTE INFLAMMATION OF THE PANCREAS, IN WHICH RECOVERY TOOK PLACE.

(Under the care of Dr. MILNES.)

THOUGH cases supposed to be examples of acute pancreatitis were described many years ago by several observers, as by Bécourt,[1] yet, as these opinions were chiefly based on naked-eye appearances found at post-mortem examinations, it is probable that in many of the cases the abnormal appearances were the result of decomposition rather than of inflammation. In fact, doubts even of the existence of pancreatitis arose, and so late as 1869 Grisolle wrote[2]: "We have still absolutely no exact knowledge of either acute or chronic pancreatitis." More recently, however, very many cases have been reported in which certain definite clinical manifestations have been found associated with unmistakable evidences of inflammation of the pancreas, as revealed at the necropsy. Unfortunately, in the vast majority of the cases the making of a diagnosis has only been possible after death, but in a certain number, where the inflammation of the organ has gone on to suppuration, the abscess so formed has been evacuated by surgical means, and recovery has followed. Many have doubted whether recovery is possible in cases of acute pancreatitis, but there can be little hesitation in admitting that such cases do occur. H. Mollière[3] expressly states that at least three cases have been observed in which the inflammation has subsided. Until the disease can be readily recognised by its symptoms, some doubt must always be present as to the accuracy of a diagnosis which has not been verified by a post-mortem examination. Judging, however, from similar inflammations in other organs, it is extremely probable that the disease is much more frequent than is usually thought, and that many cases are missed because they end in recovery.[4] The diagnosis in the following very interesting case is perfectly justifiable, and is the only one which will account for the course of the disease.

The patient, a man aged twenty-one years, was admitted into the Derbyshire Royal Infirmary on July 14th, 1896, complaining of abdominal pain and vomiting. He had always been a strong and healthy man of sober habits. His work involved exposure to great variations of temperature, and the air he breathed was usually loaded with foul gases. No history of any previous illness could be obtained. Three weeks before admission he began to suffer from pain in the lower part of the abdomen. This usually came on when he started to work after a rest and wore off as he worked. According to his own expression "his belly felt hard." About the same time the bowels became obstinately constipated. He continued to work until a few days before admission, the pain getting worse and his "belly getting harder" all the time. He took a certain amount of purgative medicine without much effect; but he did not persevere with it, and he could not remember when the bowels were last moved. On the night before admission the pain suddenly became violent and he was seized with urgent and profuse vomiting, which continued till he came to the infirmary. Dr. Cassidi, who saw him before he came in, described his condition as one of extreme collapse and as strongly suggestive of gastric or intestinal perforation. On admission, on July 14th, 1896, the patient's temperature was 102·4° F., and the usual symptoms of pyrexia were present; his pulse was 116, full, and bounding; the tongue was dry and brown; and the skin was hot and dry. The mind was quite clear, but the face was much drawn and the expression that of great suffering. He referred all his pain to the region of the epigastrium, and the condition of the abdomen was such that he could not pass urine on account of the pain caused by the attempt to micturate. The legs were not drawn up and he lay flat on his back, maintaining his posture with much stiffness. On examination the abdominal wall was found to be retracted to an extreme degree, so that the abdomen presented a concave instead of a convex surface in nearly every direction. It was stiff and quite unmoved by respiration, which was entirely thoracic and not at all hurried. The abdomen was universally and acutely tender to the touch, especially at the upper part, where even a feather-weight pressure caused severe pain. The urine, drawn by catheter, had a specific gravity of 1030; it was acid, highly-coloured, and contained a trace of albumin, but no sugar. No abnormal signs could be detected in any other organ. A third of a grain of morphia was injected hypodermically, and poppy fomentations were applied to the abdomen. Peptonised milk was ordered to be given in small and frequent doses, also four ounces of brandy daily. At 8 P.M. the pain was still severe, and an eighth of a grain of morphia was injected. On the 15th the patient passed a fair night, the pain being less severe; there had been no more vomiting, and no action of the bowels had occurred. The pulse was 110. The abdomen was still retracted, but was less tender to the touch. He was drowsy from the morphia. On the 16th he had three severe attacks of spasmodic pain in the night, which were relieved by poppy fomentations. He still complained of nausea, but there had been no vomiting. He had no pain while lying quiet in bed during the day, and the abdomen was less tender in the lower half. On the 17th he had one severe attack of pain in the night, accompanied by vomiting of bilious material. A sixth of a grain of

Digitized by Google

morphia subcutaneously appeared to give relief. There was almost no tenderness in the lower half of the abdomen, but the tenderness was still acute in the whole abdominal area above the level of the umbilicus. An enema of warm water brought away a small quantity of hard fæces. On the 18th another attack of pain in the night was again relieved by morphia injection. He still had nausea, but no vomiting. An enema was given, but was returned unchanged. A second enema brought away a good stool. On the 19th the patient had two attacks of pain in the night, one severe, and he also had two attacks of vomiting. His tongue was much cleaner, and the pulse was of good volume and averaged 100. The enema was repeated and acted well; no fat was noticed in the stools, although it was looked for every time the bowels acted. In the evening of this day the patient was suddenly seized with collapse and gasping respiration, the pulse becoming almost imperceptible. A second attack followed the first and was much more severe, and death appeared to be imminent. A hypodermic injection of three drops of liquor strychninæ seemed to revive him and he quickly recovered. On the 20th he had two further attacks of faintness during the night, but they were not nearly so alarming as the two before noted. He also had several attacks of pain, but they were not severe. He had been much better since 4 A.M. The abdominal tenderness was markedly less and was now limited to the epigastric region. One spot about two inches above and to the right of the umbilicus was specially and acutely tender. There was also tenderness in the back on pressure just below the twelfth rib on both sides of the spine. The abdominal walls were still retracted and the muscles were rigid, but not so markedly as on admission. The question of surgical interference was seriously considered, but it was decided to wait. A simple enema was ordered to be administered daily. Chicken tea was ordered to be given in addition to the peptonised milk. On the 22nd, though there had been slight vomiting on the previous day, in other respects there was great improvement. His tongue was nearly clean, the pulse was only 76, and there was no fever. The abdomen was still flat and without movement, but it was quite soft and could be handled freely without pain, except at the one spot above and to the right of the umbilicus. On the 22nd and 23rd the patient had a severe attack of pain each night, culminating in vomiting, which gave relief, and on the 24th three minims of dilute hydrocyanic acid with ten grains of bicarbonate of soda were ordered every six hours. No pain or vomiting occurred after this. The daily enema acted well, but every night the temperature continued to rise until on the 27th it reached 102·4°. The enema was then discontinued, and the evening rise of temperature quickly subsided. After six clear days the bowels began to act without artificial stimulation. On the 30th all tenderness was gone from the abdomen, which, however, was still rather flat, and did not move freely with respiration. From this date recovery was uninterrupted, and he was discharged on Aug. 31st, 1896, quite well.

Remarks by Dr. MILNES.—Those cases in which the existence of acute pancreatitis has been proved, either on the operating table or in the post-mortem room, have presented a combination of the symptoms of acute intestinal obstruction with those of perforation of the stomach or bowel. The cardinal symptoms appear to be (1) violent abdominal pain of a spasmodic character; (2) constipation, usually complete; (3) vomiting; (4) recurrent attacks of collapse during one of which the patient usually dies; and (5) the onset is generally sudden, but in a few cases the existence of colicky pain has been noted for a short time before the attack. All these symptoms were present in the above case except the fatal termination. With the exception of the case recorded by Osler, where the diagnosis was made during an exploratory laparotomy, I am not aware of any case of recovery after a diagnosis of acute pancreatitis. Osler's case, however, proves that recovery may take place. In the present case the diagnosis of acute pancreatitis was suggested to me early in the patient's illness by the acting house physician, Mr. Miles. After mature deliberation and consultation of all accessible reports I have come to the conclusion that this diagnosis is the only one that offers a reasonable explanation of the symptoms. The alternatives appear to be—(1) peritonitis of the so-called idiopathic character; (2) ulceration of the duodenum without perforation, causing sudden acute peritonitis; and (3) the passage of gall-stones, causing acute peritonitis. Intestinal obstruction and perforation of viscera are put out of the question by the progress of the case. 1. It is now generally recognised that mere peritonitis is not a sufficient explanation of any illness. There must be some local cause. In this case the local cause of the peritonitis which existed was evidently something in the upper part of the abdomen. It is difficult to suggest any local cause for acute general peritonitis in this region which would not have made its presence manifest by some further symptoms. For instance, perforation or sub-phrenic abscess must have led to events such as never occurred in this case. 2. Ulceration of the duodenum was naturally suggested by the situation of the point of maximum tenderness. The whole course of the disease, the rapid and complete recovery, and the fact that the man was quite well till a short time before the acute symptoms set in, all make against a disease which must have some period of chronicity in its course. The transient nature of the attacks of collapse and the absence of melæna show that these phenomena were not due to hæmorrhage from an ulcer. 3. Taking all the symptoms into consideration, it appears that the only way in which gall-stones could have caused this illness was by a stone becoming lodged low down in the common duct and there setting up ulceration and acute general peritonitis. If this were the case there must have been jaundice, and something must have been heard afterwards of the stone. This latter could hardly have escaped notice owing to the very strict watch kept on the stools throughout the case. Supposing this case to be accepted as one of pancreatitis, I think it adds one or two useful indications for diagnosis and treatment of future cases of a similar character. The local tenderness near the umbilicus, and still more the tenderness below the lowest ribs in the back may be sought for with advantage in doubtful cases. The history of this case further teaches us to leave the bowels alone. After admission of this patient into hospital no attacks of collapse occurred until we began to worry the bowels with enemata. Then, later, the evening exacerbations of temperature seem to have been due to the same cause, at any rate they subsided when the enemata were stopped. Among the cases recorded one is related in which fatal collapse quickly followed the administration of a purgative.

Reviews and Notices of Books.

A System of Medicine. By Many Writers. Edited by THOMAS CLIFFORD ALLBUTT. Vol. III. London: Macmillan and Co. 1897. Pp. 983. Price 25*s*.

HAVING referred on previous occasions to the object and nature of the System of Medicine, edited by Dr. Clifford Allbutt, our review of the third volume does not need any introductory remarks. The first part of this volume deals with "General Diseases of Obscure Causation," such as Rheumatism, Rickets, Acromegaly, Gout, Diabetes, &c., whilst the second contains papers on Diseases of Alimentation and Excretion.

The first article is on Acute Rheumatism or Rheumatic Fever, and is from the pen of Dr. Church. Acute rheumatism, as Dr. Church remarks, is a disease more easily described than defined, and he therefore considers the disease as equivalent to a synovitis accompanied by pyrexia and generally multiple. Such a description shows the courage of the writer, for by it he admits that the exact nature of the disease has not yet been discovered, although it is so widely diffused and occurs with such frequency, as is shown by some carefully compiled statistics accompanied by tables contained in appendices to the paper. In speaking of the etiology Dr. Church remarks that although no satisfactory evidence has as yet been procured of the constant presence of any single specific micro-organism, yet in not a few of its features the whole course of rheumatic fever resembles an infective disease; moreover, the curves of its mortality statistics in this country approximate very closely to those of pyæmia, puerperal fever, and erysipelas—diseases which are certainly associated with specific micro-organisms. The

Digitized by Google

evidence in favour of the chemical theory of acute rheumatism is considered to be unsatisfactory, as is also that in connexion with the nervous theory. Attention is drawn to the influence of fatigue and exposure in a dry and otherwise salubrious climate, as shown by the military returns during the Egyptian and Cape wars. The subject of hyperpyrexia is also fully dealt with.

The section on "The Acute Rheumatism of Childhood" is by Dr. Cheadle whose experience in the diseases of children makes his remarks of great value. He first draws attention to the differences between rheumatism as it occurrs in childhood and as it appears in maturer life, especially as regards the occurrence of cardiac complications. He also remarks that the series of rheumatic events is often spread out and scattered over a term of months or years, so that the history of a rheumatism may be the history of a whole childhood. At one time, for instance, there may be an endocarditis, a chorea at another, and an arthritis at another, without any further coincident manifestation of the disease. The difficulties of diagnosis are pointed out, especially as regards mistaking infantile scurvy for acute rheumatism. Dr. Cheadle also argues that mitral stenosis is the special product of the sub-acute, slow, recurrent course which is so characteristic of endocarditis in childhood; but the auscultatory evidences usually do not appear until some years later, when the disease is advanced and the mitral orifice has become permanently narrowed. Another exceptional and special feature of acute rheumatism in children is the development of subcutaneous nodular growths of fibrous tissue. This subject is most ably dealt with, stress being laid on their connexion with changes going on in the fibrous tissues of the cardiac valves or pericardium.

Dr. Archibald Garrod is responsible for the next three articles—namely, those on Chronic Rheumatism, Muscular Rheumatism, and Gonorrhœal Rheumatism. Dr. Garrod's writings are usually characterised by plainness and absence of unnecessary details, and these articles are no exception to the rule. The sections on Treatment are particularly worthy of perusal. The author favours the hypothesis that the so-called gonorrhœal rheumatism is due to a specific systemic infection of the gonorrhœal virus.

The important subject of Rheumatoid Arthritis was undertaken by Dr. Kent Spender, but before he had completed or revised his essay he was compelled to relinquish his task owing to a heavy affliction. Dr. Garrod undertook to revise and finish the work. A full description is given of bacterial investigations which have been made of the fluid from the diseased joints, and these would seem to show that some, at any rate, of the cases included under the name of rheumatoid arthritis actually owe their origin to a specific organism. Attention is drawn to the muscular atrophy of rheumatoid arthritis, which is often independent of the mischief in neighbouring joints. Dr. Spender also describes minutely the disturbances in the skin which he has observed in patients suffering from this disease, and which he believes to be an important diagnostic sign in doubtful cases. A short paper on Rheumatoid Arthritis in Children by Dr. G. F. Still is interesting.

An excellent account of Rickets is given by Dr. Cheadle. The morbid anatomy and histological features are fully and clearly described, as are also the changes which the organs of the body generally may undergo in connexion with this condition. The author sums up his conclusions thus: "Rickets is a disease in which all the leading structures of the body suffer both from defective and from perverted nutrition. This is mainly the results of faults of diet, and consists in a deficiency of certain elements in food. ..... The chief and constant defect appears to be an insufficient supply of animal fat, and therewith also, in certain cases, a deficiency of earthy salts in the form of phosphates; at the same time, if animal proteid be deficient the disease is intensified. ..... The disease is modified in character by the concurrent existence of congenital syphilis or of scurvy."

Mr. Anthony Bowlby is the author of articles on Osteomalacia, Osteitis Deformans, Acromegaly, and Hypertrophic Pulmonary Osteo-arthropathy. Mr. Bowlby is well qualified to write on these conditions, and the only fault we have to find with the articles is that they are too short. Our knowledge of the latest of joint affections with the unwieldy name of hypertrophic pulmonary osteo-arthropathy has considerably increased since Mr. Bowlby wrote his contribution, the x rays and more necropsies having materially altered the views formerly held as regards its pathology.

One of the best articles in this volume is that on Gout, by Sir William Roberts whose researches on the chemical pathology of the "gouty state" have added so much to our knowledge. In his present contribution the author has summarised what is known of the symptoms, etiology, morbid anatomy, pathology, and treatment of gout, and, needless to say, the result is admirable. He lays stress on the conditions "uratæmia" and "uratosis." Uratæmia is not confined to gout, whilst uratosis is. Uratosis cannot occur, so far as is known, without coexisting uratæmia, but it is certainly true that uratæmia may exist for long periods without provoking the occurrence of uratosis.

Dr. Robert Saundby's contribution on Diabetes Mellitus is also a valuable one. His remarks on treatment are especially worth reading. Practitioners will do well to note his directions as to the management of diet. The pathology of the disease is well discussed, and the author's observations on the condition of the pancreas are an addition of considerable value. Phenyl-hydrazin is recommended as the best test for sugar.

Diabetes Insipidus is described by the late Dr. Ralfe whose death has deprived the profession of one of the best authorities on urinary disorders from a physician's point of view. He discusses the classification of diabetes insipidus by Willis and Parkes, and then refers the increased excretion of urinary water and of normal urinary solids respectively to two classes: (*a*) that in which the aqueous superflux is most marked—hydruria; and (*b*) that in which the drain of one or more of the solid constituents of the urine is persistent—polyuria. Each of these divisions is then fully described, showing a large amount of original observation and research.

Dr. Howship Dickinson writes an interesting paper on Lardaceous Disease. Especially interesting are the tables analysing the causes of this condition. The author's sketch of the etiology of the disease is based on a collection of 201 cases obtained from the post-mortem and case books of St. George's Hospital. Suppuration is presented in 167 of the cases—that is, in over three-fifths. Syphilis was the ostensible cause in twenty-three, or in about one-ninth.

Passing to the second division of this volume we come to "Diseases of Alimentation and Excretion." The "General Pathology of Digestion" combines the writings of the late Dr. Ralfe and Dr. W. Soltau Fenwick, whilst the "General Pathology of Secretion" is in the able hands of Dr. J. R. Bradford. Space will not allow us to comment on these two sections, but Dr. Bradford's remarks on the Thyroid Gland will doubtless receive considerable attention.

A good deal of original observation is found in Mr. Louis Cobbett's contribution on Shock and Collapse, whilst Dr. W. A. Wills's description of Diseases of the Mouth is fully up to date. Dr. H. D. Rolleston has evidently taken a good deal of trouble with the rather unsatisfactory subject of Diseases of the Œsophagus. With the exception of stricture of the gullet very little is known concerning such diseases, but œsophagitis deserves more attention than is usually devoted to it in ordinary text-books. Dr. Lauder

Digitized by Google

Brunton's writings on digestive disorders are well known; needless to say, therefore, that his article on Dyspepsia in this volume will well repay perusal, especially his remarks on treatment. Dr. W. Soltau Fenwick contributes a short paper on Dyspepsia in Childhood, to which subject he has devoted much attention. The subjects of Acute and Chronic Gastritis are dealt with by Dr. Brunton, and then follows a series of papers on rarer morbid conditions of the stomach by Dr. R. F. C. Leith. The diseases referred to are scarcely mentioned in most books. Dr. Leith gives a full description of their symptoms and pathology. He is to be congratulated on the success with which he has carried out his difficult duties. He first describes Phlegmonous Gastritis—a severe inflammation passing on to purulent infiltration of the stomach wall; next Membranous Gastritis; then the changes produced in the stomach by the ingestion of poisonous doses of various substances (chiefly metallic) or Toxic Gastritis; then follows Gangrene of the Stomach; and, finally, Cirrhosis of the Stomach.

Dr. J. R. Stocker contributes an able article on Seasickness. He proposes an entirely new theory as to the cause of this unpleasant malady; he says: "The difference, then, between a good sailor and a bad one appears to me to be mainly in the difference in their mode of respiration, and the cause of the complaint seems to be seated neither in the stomach nor in the brain, but in the throat."

From his own personal experiences Dr. Clifford Allbutt is able to provide an interesting discussion on Mountain Sickness, but the reports of Sir Martin Conway, Mr. Whymper, and Mr. Clinton Dent are duly recorded. Dr. Allbutt considers that deprivation of oxygen suffices to explain all the essential phenomena of mountain sickness. Dr. Allbutt also writes on Neuroses of the Stomach and Dilatation of the Stomach. His vivid descriptions of symptoms drawn from cases which have been under his own observation are particularly attractive, and both articles are of the highest merit, containing much original thought. We would especially draw the reader's attention to the pathology and treatment of dilatation of the stomach. Carefully compiled articles on Ulcer of the Stomach and Ulcer of the Duodenum, by Dr. Dreschfeld, follow and contain many practical hints as to treatment drawn from the writer's own experience. Dr. Hale White writes on Tumours of the Stomach, primary carcinoma naturally occupying most of the space. The difficult subjects of subphrenic abscess and diaphragmatic hernia are dealt with by Dr. Lee Dickinson. Dr. W. S. Playfair contributes a useful paper on Abdominal Diagnosis from a Gynæcological Standpoint. Mr. Frederick Treves's paper on Enteroptosis concludes this section of the book.

Diseases of the Peritoneum hold the next place, and Mr. Treves opens the subject by an excellent contribution on Acute Peritonitis. Mr. Treves's style of writing is well known, and this paper will in no way detract from his reputation as an author who knows what he is writing about and has the power of conveying his knowledge to others.

The next four articles are by Dr. Allchin: Acute Peritonitis of Undetermined Nature, Chronic Peritonitis, Tubercle of the Peritoneum, and New Growths of the Peritoneum. These are fully up to the standard of the other papers already noticed, and want of space alone prevents us from commenting on each of them separately. They will be found most useful for reference, containing, as they do, all the latest views on the subjects described.

In the section of "Diseases of the Bowels" are several well-written articles: Physiology of Fæcal Evacuation, by Dr. Lauder Brunton; Diseases of the Small Intestine, by Dr. H. D Rolleston; Colic, by Dr. Hale White; Diarrhœa, by Dr. Lauder Brunton; Diarrhœas of Children, by Dr. Eustace Smith; Sprue or Psilosis, by Dr. Patrick Manson; Intestinal Obstruction, by Mr. Treves; Diseases of the Colon, by Dr. Hale White; and the Differential Diagnosis of Diseases of the Anus and Rectum, by Mr. Herbert Allingham.

Medical Climatology. By Dr. S. EDWIN SOLLY, Late President of the American Climatological Association. 1897. London: J. & A. Churchill. Pp 470. Price 16*s*.

THIS is a very complete work on Medical Climatology, well written and containing a large amount of information. The whole subject is dealt with in a scientific spirit, and it is very far from being simply a guide-book or a mass of statistics. The subject matter is divided into three sections. The first of these deals broadly with the principles of medical climatology, and describes the close connexion of this science with physics, meteorology, ethnology, and "geographical pathology." The second section treats of the therapeutics of climate in relation to disease, and it is this section that will especially interest English physicians. As the author states in his preface, no attempt has been made under this head to prescribe special climates for special diseases, and it is obvious that as considerations so many and so different enter into the adaptation of the individual case to the particular climate, this would be a futile effort. The third section is devoted to a description of special climates as typified in selected resorts, and includes comparative and other tables.

The first division is brief, but to those who study climatology will prove interesting. The second section deals mainly with the climatic treatment of pulmonary tuberculosis; this is natural, as being the most important of these diseases in which climate has to be especially considered. We have never read in any other work a more complete consideration of the effects of climate upon this disease than is given by Dr. Solly. He discusses the subject upon a pathological basis and shows the effect upon the tuberculous process of pure air, sunlight, sunheat, temperature, humidity of the soil and air, variability of temperature, mobility of atmosphere, altitude, &c. The actual changes in the blood produced by altitude are then noted, and some remarks follow on the general therapeutic effects. The effect of climate upon pulmonary tuberculosis in its various stages is described, and general conclusions are arrived at as to the class of case suitable for various resorts. Other forms of disease influenced by climate are also described.

The section of the work devoted to an account of special climates is occupied mainly with a very full consideration of American climates, 182 out of 266 pages being thus taken up. The British Isles are dealt with in about eleven pages; most of our health resorts are, indeed, mentioned, but only a few lines are devoted to each. For English medical men who have patients who cannot leave England, this is disappointing. The part dealing with the Riviera is limited to five pages. The American climates, on the other hand, are most excellently described and illustrated with maps, the "relief maps" especially being most beautifully executed. Taking the book as a whole, we consider it to be a good work of reference on climatic resorts, as well as one conveying much information on climate considered from a scientific point of view.

Crime and Criminals. By Dr. J. SANDERSON CHRISTISON. Chicago: The W. T. Keener Company. Pp. 117. 1897. Price $1.

THIS book consists of a series of sketches of various types of criminals, and is illustrated with numerous copies of photographs of criminals and lunatics, and also diagrams of brains. Three essentially different classes of delinquents are described, viewed from a psychological standpoint—viz., the insane (defective in reason), the moral paretic (defective

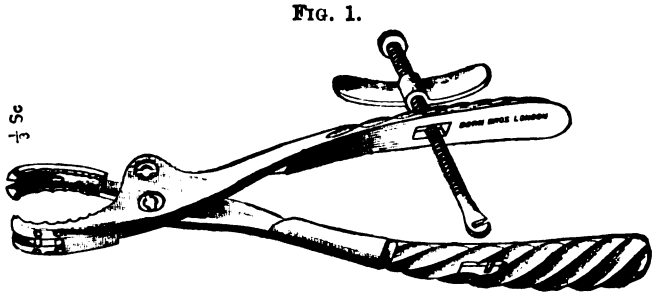
Digitized by Google

in self-control), and the criminal proper (defective in conscience). Twenty-three cases are described illustrating the characteristics of criminals imprisoned for various crimes — from picking pockets to murder. For those interested in the so-called new science of criminology this book will have a considerable attraction. It is well written, although the American expressions occasionally strike an English reader as being quaint. For instance, Case 19 is a "safe-blower" now serving his third term in the penitentiary at Joliet; it is stated that the prison officers "regard this prisoner as one of the brainiest and smartest now in the prison."

Manual of Mental Diseases. By A. CAMPBELL CLARK, M.D. Edin., F.F.P.S. Glasg., Mackintosh Lecturer on Pyschological Medicine, St. Mungo's College, Glasgow; Medical Superintendent of Lanark County Asylum, Hartwood. University Series. London: Baillière, Tindall, and Cox. 1897. Demy 8vo, pp. 484. Price 10*s.* 6*d.*

DR. CAMPBELL CLARK has no faith in the stereotyped apology with which so many books are prefaced, but tersely states that his work must stand or fall on its merits. Merits it has many, and defects not a few. The author makes the somewhat sweeping assertion that the pathology of insanity does not exist and has yet to be written. He has the courage of his opinions, and has ruthlessly excluded all reference to pathological data. In this respect we venture to think he has erred. Comparisons are proverbially odorous, but we could have wished that the author had followed more closely the lines of Dr. Clouston's work on Mental Diseases, in which the subject of pathology occupies a deservedly prominent place. The influence of the teaching of this distinguished alienist is evident throughout the present manual; his opinions are frequently quoted and as freely acknowledged. No doubt Dr. Clark is well advised in omitting from his work the highly speculative and exaggerated theories which have been advanced regarding the pathology of many mental disorders, but surely the pathology of such a disease as general paralysis is sufficiently well known and established to merit inclusion even in a practical text-book like this, which is professedly written in the main for the use of students. In its clinical aspect the work is deserving of much praise; the cases detailed have evidently been selected with care, but we cannot express unqualified approval of the dialogue method which has been adopted in several instances, nor can we say much in favour of the photographic illustrations.

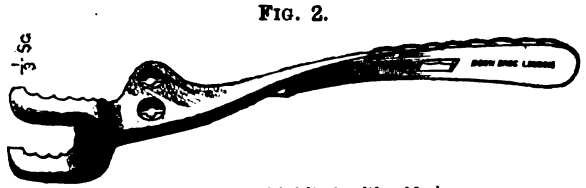
The introductory chapters are devoted to the study of mental constitution and mental character, including mental health. Insomnia and its treatment are dealt with at some length, and this section will repay perusal. The part dealing with causation, prognosis, and treatment is distinctly good. Dr. Clark utters a note of caution regarding the lax way in which the causation of insanity is sometimes discussed, and states that, as a result, the general public imagine they know all about it, and are convinced that two factors account for everything—heredity and alcoholic excess. Under the heading of Treatment we find that his experience of the thyroid extract, except in cases of myxœdema, has been disappointing. The various recognised forms of insanity are lucidly discussed in detail, and their explanation is materially assisted by a series of carefully selected clinical cases and by a number of excellent charts. Perhaps the best chapter is that on Evolutional and Dissolutional Types. Here the author speaks with authority, and he gives a remarkably clear exposition of the mental disorders which are liable to occur in earlier and later life—those due to the physiological stress and strain of puberty and adolescence and those incidental to the approach of the climacteric and the decadence of old age. Not less important are his remarks on the insanities of pregnancy and lactation and also on puerperal insanity. The practical value of these chapters is very considerable. The mental disorders associated with various forms of bodily disease are fully dealt with, the legal and civil relationships of insanity are pointed out, and copies of the various lunacy forms in use in England, Scotland, and Ireland are appended.



The volume is handsomely bound, well printed, and possesses a carefully prepared index. The book is lucidly written and the meaning clearly expressed. It is intended for the use of general practitioners and students, and to the general practitioner we cordially recommend it. He will find it handy and useful for reference and of much practical value.

New Inventions.

LION FORCEPS FOR USE IN SCREWING, WIRING, AND OTHER OPERATIONS ON BONE.



WIRING, screwing, and other devices have been successfully employed by Mr. Arbuthnot Lane and others for the purpose of securing correct apposition of fractured bones and their retention in this position. The results so obtained encourage a further use of these methods and particularly their application to fractures in the neighbourhood of joints. The precision to be attained by these methods is more fully recognised when accurate drilling previous to the deposition of wires and screws is made easy. To meet the requirements in such operations I have devised the above-mentioned instrument which has been referred to by Mr. Lane in his paper in the *Clinical Journal*. Essentially the forceps is a modification of Farabœuf's lion forceps and can be used for all the purposes of a lion forceps. It is further fitted with a detachable approximating screw and an additional limb suitable for the passage of screws or, in certain cases, of wire. A drill grooved along its length with a trocar point is adapted for use with the instrument. Both jaws of the forceps are sawn longitudinally so as to allow wire to be passed free of the forceps. The upper jaw is drilled with holes in two series, the one series being adapted for larger and the other for smaller bones. By this arrangement it is possible to drill a hole in any position up to 40° from the vertical in either direction. This varying angle of impact is obtained by conical holes on either side of the central saw slit. The saw slit is also conically enlarged at suitable points

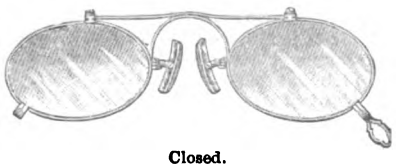
FIG. 1.

The forceps used with the two narrow-jawed blades.

FIG. 2.

The additional or third limb with wide jaws.

Digitized by Google



to accommodate the drill without allowing it to slip. The third limb (Fig. 2) has a large forked extremity which will allow of the manipulation of any drill and screws. The forceps can be used either for drilling the two bones in position and subsequent wiring without relaxing hold, or for boring a single piece of the fractured bone. It is so arranged that a wire can be passed from the central slit into the holes in the bone which have been drilled through the side holes of the forceps. If, therefore, one of these lateral holes of the forceps is used to direct the drill, the wire can be adjusted without removing the forceps. The main points connected with the forceps are: 1. A firm grip can be obtained on one or more fractured fragments, and the forceps retained in position by the approximating screw. 2. The drill can be passed precisely, rapidly, and without fear of slipping. 3. The wire or screw can be passed and adjusted without removing the forceps. 4. The instrument can be used as ordinary bone forceps.

The instrument is made by Messrs. Down Bros., to whom my thanks are due for the care they have expended on its manufacture. E. A. PETERS, M.B., B.C.

AN IMPROVED PINCE-NEZ.

THIS new form of pince-nez—the "Revluc"—should recommend itself to those who have a preference for "glasses" of this description. As will be seen from the illustration, placquets are affixed to the periphery of the eye frame next the nose, and are automatically adjusted by means of a spring bridge. The pressure on the nose is firm, but not great enough to cause discomfort or to mark the skin; and there is no tendency of the glasses to tilt forward, an important

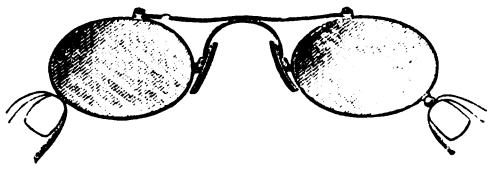


FIG. 1.

Closed.

consideration when, as in the case of astigmatism, the lenses require to maintain a definite position with respect to the eye. A two hours' ride on a bicycle over a moderately bad road is a severe test for any kind of pince-nez, but this the Revluc has stood without becoming displaced. The combination of bridge and horizontal bar strengthens the frame without appreciably increasing its weight, and at the same time ensures the centres of the lenses being always properly

FIG. 2.

Open.

adjusted to the distance between the pupils. The illustrations will show the neatness of appearance and simplicity of construction perhaps better than words; but we may point out that the absence of spiral springs, which have a tendency to collect dust always difficult to remove, enables the frame to be kept clean with little difficulty. The Revluc is manufactured by Mr. George Culver, White Lion-street, Pentonville, London.

THE JENNER MEMORIAL MEDAL.

ON the occasion of the Jenner Centenary it was thought, as was pointed out at the time by the President, that the Epidemiological Society should take some steps which, while celebrating an event of such importance to preventive medicine, would at the same time do something to promote the study of epidemiology at the present time. It was finally decided to found a medal in memory of Edward Jenner, to be conferred by the society from time to time for work of great merit, and a sub-committee, consisting of the then President (Mr. Shirley Murphy), Sir Richard Thorne Thorne, K.C.B., F.R.S., Fleet-Surgeon Theodore Preston, R.N., and Dr. Frank Clemow, together with the treasurer and honorary secretaries of the society, was appointed to consider the design of such medal. This sub-committee, which, on the retirement of Mr. Shirley Murphy from the presidency, had the further advantage of Surgeon-Colonel Lane Notter's advice and experience, finally recommended the society to accept a design submitted by Mr. Allan Wyon, F.S.A., who is now engaged in executing the necessary dies. In the next volume of the Transactions of the society it is hoped that a facsimile of the design for the medal will be presented.

It was thought by the society, in founding a memorial of this nature, that the medical profession in general should be afforded an opportunity of subscribing to the original cost, and it is a matter for congratulation that the response to the appeal which the society made through the medical journals has enabled the dies to be procured at a merely nominal expenditure on the part of the society. The medal, too, from the fact that it was founded by subscription from many parts of the world, cannot fail to be more highly appreciated by the recipients of it than would have been the case had it been founded by the society alone. Below is the list of the subscribers to the fund.

List of Subscribers to the Jenner Memorial Medal.

The Epidemiological Society of London.
Dr. Henry Armstrong.
Dr. Robert Barnes.
Mr. F. Blackwell.
Dr. F. T. Bond.
Dr. W. A. Bond.
Sir William Broadbent, Bart.
Mr. M. Brownfield.
Dr. H. Timbrell Bulstrode (Hon. Sec. of Epidemiological Society).
Dr. Claremont.
Dr. F. Clemow (Cronstadt).
Dr. A. E. Cope.
Mr. Bolton Corney (Fiji).
Dr. Andrew Davidson.
Dr. Dickson (Constantinople).
Dr. Donnett, R.N.
Surgeon-Captain Drake-Brockman (Bombay).
Dr. W. W. E. Fletcher.
Mr. Andrew Fuller.
Dr. E. W. Goodall.
Dr. E. Goddard.
Surgeon-General Sir C. A. Gordon, K.C.B., Q.H.P.
Mr. E. C. Greenwood.
Mr. A. L. Griffiths.
Mr. Grigg.
Dr. S. Hague.
Dr. Hamer.
Dr. Hare.
Dr. Harrison.
Dr. E. Hibberd.
Dr. W. F. Hingston.
Surg.-Gen. Sir Anthony Home, K.C.B., V.C.
Dr. B. O. Hopwood.
Dr. W. Hunter.
Mr. V. Jaynes.
Dr. Joseph von Koröse (Budapest).
Dr. J. Little (Dublin).
Mr. J. Loane.
Dr. G. B. Longstaff.
Dr. J. C. McVail.
Mr. G. A. Miskin.
Mr. T. Mitchell.
Dr. Müller (Budapest).
Mr. Shirley Murphy.
Surgeon-Colonel J. Lane Notter (President of the Epidemiological Society).
Mr. J. Norton
Sir James Paget, Bart.
Dr. Louis Parkes.
Dr. Franklin Parsons.
Dr. J. F. Payne.
Fleet-Surgeon Theodore Preston, R.N.
Dr. Pye-Smith.
Mr. T. F. Rogers.
Mr. M. G. Roundtree.
Dr. Saltet (Amsterdam).
Dr. Sansom.
Sir Edwin Saunders.
Brigade-Surgeon J. B. Scriven.
Dr. Edward Seaton.
Sir John Simon, K.C.B., F.R.S.
Dr. Smart.
Dr. Sonsino.
Dr. Sweeting (Hon. Treasurer).
Dr. Theodore Thomson.
The late Sir J. Tholozan, K.C.M.G. (Teheran).
Sir Richard Thorne Thorne, K.C.B., F.R.S.
Mr. Thomas Wakley, Jun.
Dr. J. W. Washbourn.
Mr. S. Welsh.
Dr. William Williams.
Dr. S. Wheaton.
Dr. B. A. Whitelegge.
Dr. J. T. Wilson.
Dr. C. W. F. Young.

SHEFFIELD ROYAL INFIRMARY.—The annual meeting of the Sheffield Royal Infirmary was held on Sept. 1st, Sir Alexander Wilson, Bart., the retiring Master Cutler, being in the chair. The report stated that next month—namely, on Oct. 4th—the infirmary will have completed a century of its existence, and that the new buildings erected in commemoration of the centenary year are approaching completion. Last year, on the occasion of the Queen's visit to Sheffield, she was graciously pleased to confer upon the institution the title of the Sheffield Royal Infirmary. The house surgeon's report showed that 1869 in-patients, 4103 out-patients, 12,933 casualties, and 2190 dental cases had been treated during the year. The number of beds now available is 202, of which 44 are devoted exclusively to children's cases. The amounts received from the Hospital Sunday and Hospital Saturday Funds were £1095 and £722 respectively. The expenditure had exceeded the ordinary income by £1198. One of the speakers mentioned that something like £5000 was still required to complete the centenary commemoration buildings and the furnishing.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 11, 1897.

THE meeting of the British Medical Association in Montreal, or, rather, the opening address of the distinguished President, Dr. RODDICK, Professor of Surgery in the McGill University, has called forth a somewhat severe criticism on the Association from the *Times* which cannot altogether be disregarded. The address and the criticism form an interesting illustration of the different conclusions to which men may come who are presumably equally able and disinterested, showing, as most such illustrations do, the importance of difference of standpoint and of the colour of the medium in which the object is seen. The address, or, rather, that portion of it which seems to have called forth the uncomplimentary side of our contemporary's criticism, was spoken from the President's chair and dealt naturally enough with the noble objects of the Association, its impartial constitution, its accumulating capital, and its great numbers "of earnest men pitted against false dogmas and ever battling for the truth." For such an Association the President could see no future but one of increasing power and usefulness. It was beyond his conception that any age could come which would cease to feel its benign and mighty influence making for the amelioration and elevation of mankind. He even expressed his belief that it would be an important factor in bringing to a successful issue that great scheme of Imperial Federation which now exercises the mind and hearts of the leading statesmen of the empire. What must have been the President's feelings when he opened the *Times* of Sept. 1st to learn that all his eulogy of the Association and its power was a mistake—"the truth being that the absence of such power and influence is one of the most remarkable characteristics of the organisation, and one which has often occasioned much perplexity to those who have been called upon to consider its proceedings." Nor is this the worst that the candid article in the *Times* had to say, for from other passages we learn "that probably no statesman was ever influenced by its [the Association's] views with regard to any matter of legislation," that it "has made some microscopic pecuniary grants for the promotion of scientific research and that nothing very important has ever come of them"; that even at the annual meetings of the Association recreation is generally preferred to science; and that all the work of the profession, whether scientific, charitable, or administrative, is done by independent societies. No English President, concluded the *Times* in leaving that aspect of the question, could have employed the language which Dr. RODDICK used "without, at least, being suspected of irony."

The weakness of the profession is its want of cohesion and concord, of organisation and unity. There are not wanting signs of still more and graver cleavage into sections and coteries. The one great and indivisible profession is to be broken up into bits or into classes. It is a responsible thing in the face of such facts to disparage the greatest association of the profession, and we cannot but ask ourselves what explanation can be offered of such disparagement, and, if possible, what excuse. We have never been blind admirers of the Association. There have been many things in its history which have been unworthy of its very greatness—partialities, personalities, timidities, and favouritisms. It has not always had a soul to call its own. Last year two of the oldest members of the Association, who have since respectively been solaced by the gift of its gold medal, were allowed to drift out of the position of direct representatives in the General Medical Council when a little early and firm support from the Association of which they had been lifelong supporters would have secured their honourable return. Of late years the annual meetings have been less attractive than of old, not so much because of the prevalence of "recreation"—a most legitimate and desirable part of the duty of gatherings of scientific men—or because of the subordination of medical science to so-called medical politics, but because of the abstention from the councils of the Association of those whose influence and whose character would have given them a status from which to deal alike with the demands of medical politics, of medical science, and of medical ethics.

It is impossible to deny these facts with regard to the Association or to shut our eyes to their gravity. But when all has been said we cannot deny the usefulness of the Association or doubt that it has materially affected both medical and sanitary legislation and medical science. Its numbers are great. If its deliberations have not directly affected the laws of the nation to the extent that we might naturally have expected they have at least educated the rank and file of the profession and so, in an indirect manner, have instructed the public at large; and from the position of an improved popular opinion to an improved legislation is generally but a short step. The Association includes nearly half the profession, and even if it never realises the ideal which Dr. RODDICK has painted it necessarily has before it an important future. But it must work conscious of what that future is to be. It must be calm and well ordered. It must have set purposes and a defined scope. In this way its members may know what to expect from it, and by insisting upon taking an active part in its conduct may vivify it and mould it to greatness.

WHAT, we wonder, will Lord HERSCHELL and the other members of the defunct Royal Commission on Vaccination think of the manner in which their posthumous Sixth Report has been presented to Parliament and the public. Of the 187 witnesses whom the Commission examined during its seven years' labours this huge blue-book contains the minutes of evidence of no less than 83. It runs to nearly 800 double-columned and closely printed foolscap pages, and contains, in addition, many maps and diagrams. It will hardly be believed that such a volume has been issued by Government without an index of any sort to help Members of Parliament, or the medical profession, or the anti-vaccinationists, either to digest its contents or to find in it reference to any particular point regarding which they may wish to consult it. It is true that the "Final

Digitized by Google

Report (issued many months before this one) was without an index, but the difference between the final report and this report as regards need for guidance is greater than the difference between the king's highway and the maze at Hampton Court. The previous volumes of evidence were much less in size than this one—the four contained amongst them the evidence of only about a hundred witnesses—but each of them was furnished with an ample and excellent analytical index.

What may be the cause—reason there can be none—for this extraordinary neglect we do not know. Most certainly it has not been want of sufficient time to prepare an index, for the evidence recorded in the volume began in November, 1891, and ended in December, 1893. That is nearly four years ago. Moreover, the preliminary note, the so-called "Report," in which the Commissioners submit the evidence to HER MAJESTY, is dated Feb. 14th, 1896, or more than a year and a half ago. In the latter part of the last Session of Parliament questions were repeatedly asked as to when the Report and Appendices would be published. In reply a time was mentioned, and after the promised publication was considerably overdue the matter was again made the subject of question and answer. Now, at length, when Parliament is not sitting, and no question can be asked, the huge tome is placed before the public in such a fashion that the irate reader would be glad to know on whom the responsibility for the form in which it appears rests.

It is simply out of the question to permit this volume to be placed on the library shelves of the country unaccompanied by a good index, and if none is issued in supplement before Parliament meets steps will have to be taken then to press the Government to give the necessary order. We need only mention that the list of witnesses, in addition to containing the names of various leading opponents of vaccination, includes those of Dr. BARRY, Dr. BIRDWOOD, Dr. J. H. BRIDGES, Dr. MONCKTON COPEMAN, Dr. R. J. B. CUNNYGHAME, Dr. HIME, Dr. HUSBAND, Dr. KLEIN, Mr. MCFADYEAN, Dr. J. C. MCVAIL, Dr. OGLE, the late Dr. BEAVAN RAKE, Dr. FREDERICK TAYLOR, Dr. WHITELEGGE, and Dr. SIMS WOODHEAD. No doubt it will take a good deal of trouble to prepare an index, which, judging from those of previous volumes, ought to run to some fifty pages or thereabouts. It cannot be supposed that the Commission would spend two years listening to evidence, and give the eighty witnesses all the labour of preparing it, and yet would in the end fold its hands and declare that it could not supply an index of what these witnesses had said. The matter is justifiable from no point of view. It is a sheer waste of paper and printing and lithographing to send forth a report (costing 14*s*.) without its ordinary and necessary accompaniment. And in the interests of the literature of science it is essential that even yet an index should be published. We strongly suspect that when the Commission ceased to exist as such there must already have been made some more or less complete digest of the contents of this volume. This, indeed, is bound to have been the case, for the Final Report could not have been prepared without it. This digest must be pigeon-holed somewhere. But when the Commission was dissolved, its Final Report being issued, it seems to have been nobody's business to attend to the issue of a great bulk of valuable material on which that Report was largely based. For it must be recollected that not only is there this mass of evidence taken directly by the Commission, but there are also the very important special reports on the small-pox outbreaks which occurred in Dewsbury, Gloucester, Warrington, London, and Leicester, and which were investigated by Dr. SIDNEY COUPLAND, Dr. SAVILL, and Dr. LUFF. Then, also, Dr. THEODORE DYKE ACLAND made inquiry into many cases of alleged injury from vaccination. All this has to be published and all this has to be indexed. In so far as these special reports will be much less voluminous than the minutes of evidence now issued their indexing will be easier, but none the less the duty should not be left to the public. If there is now no one responsible for all this work then it is imperative that some one should forthwith be appointed. The delay that has already taken place is much to be regretted, but that the long-waited-for reports should in the end be launched like ships without rudders or compasses is indefensible.

THE Commissioners of Prisons are to be congratulated on the many satisfactory features of the present report. It breathes a spirit of progressive and enlightened policy which augurs well for the future. Amongst other things which have occupied the attention of the Board may be mentioned the treatment of juveniles on special lines, the segregation of first offenders, the differentiation of the occasional from the habitual criminal, the care and treatment of the weak-minded, and the better preparation of convicts for liberty. All these are steps in the right direction. The number of training schools for prison officers has been increased, and a scheme for the future organisation of aid societies throughout the country has been framed. The numbers of the prison population continue to decrease, and there has also been a satisfactory diminution in the number of the criminal insane. The vexed question of insanity in prisons, on which of late so much attention has been concentrated, and regarding which much ignorance has been displayed by writers innocent of any practical knowledge of the subject, bulks largely in the remarks of the Commissioners and also in the notes of the medical inspector. The matter is discussed at considerable length, and reports from the governors and medical officers of the various convict prisons are given, which should tend to allay the public apprehension concerning the alleged injurious effect of penal servitude on the mental health of prisoners. Anyone who cares to peruse the factors of insanity as set forth in the annual reports of the Commissioners in Lunacy cannot fail to observe that the convict is shielded from the operation of the most dangerous of the insanity-producing causes. His life is regular, his diet is wholesome, he is not over-worked, and his labour is, for the most part, done in association and in the open air; he has a plentiful supply of books, and he is under continual medical supervision. All these are conducive to sanity, and without doubt exercise a beneficial effect on prisoners who are predisposed to mental deterioration. It must be borne in mind that many of these men have led vicious lives, and have contracted disease,

Digitized by Google

the insidious and damaging effect of which on the nervous system is well understood; a proportion also are hereditarily tainted, the degenerate offspring of degenerate parents. Possibly the strain of imprisonment on the nervous system is greatest during the first months of imprisonment—during the period of separate confinement. Nowadays a sentence of penal servitude is the measure of punishment awarded for a crime of some magnitude; in connexion with this, the period of suspense before trial, the excitement of the legal proceedings, the subsequent reaction, and the prolonged process of introspection which necessarily follows, are calculated to exercise a somewhat disturbing effect on the higher levels of the nervous system, and in persons of unstable nervous organisation the results may in some instances be unfavourable. The Commissioners, however, with commendable forethought, have foreseen this contingency, and have directed that any prisoner who shows the slightest premonitory symptoms of nervous disorder shall be specially treated, and, if necessary, removed to a prison where he may have the benefit of associated outdoor labour. It is apparent that the authorities are displaying an anxious solicitude for the protection of the criminal in all that pertains to his mental well-being.

Dr. SMALLEY, the new medical inspector who succeeded to the post on the resignation of the late Dr. GOVER, contributes an interesting summary of the year's work in the medical department. In the local prisons, excluding executions, suicides, and one accident, the number of deaths was 104, giving a death-rate of 7·4 per 1000, which is slightly higher than that recorded last year. Death supervened in less than a month after reception in 41 cases, or 2·9 per thousand. This is more than a third of the total number of deaths, and indicates the wretched state of health in which prisoners are often received into prison. In 45 cases pulmonary disease in one form or another was the cause of death. Heart disease proved fatal in 18 and kidney disease in 12 instances. There were five suicides. Considering the large number—namely, 175,604—of all sorts of men and women received during the year this number is small and speaks well for the vigilance and supervision exercised. Seventy-five prisoners were released on medical grounds; they include the cases of 44 females released on account of advanced pregnancy. Dr. SMALLEY deals with the question of insanity in prisons in a clear and convincing manner. He shows how futile it is to attempt a comparison between the rate of lunacy in the prisons and that of the general population, the conditions being so different and so unequal. The number of cases of insanity in local prisons was 380, a decrease of 98 as compared with the number last year; of this number, however, 216 consisted of prisoners either unconvicted or remanded for observation, or found insane on arraignment, or found "guilty but insane" at their trial. Hitherto it has been the custom to include these cases and also the cases of prisoners found insane in prison after conviction in one table—a method which showed an unduly large proportion of insane to the prison population. Hence arose in great measure those erroneous impressions based on false deductions which tended to raise alarm in the public mind. It is neither reasonable nor fair to include the cases of unconvicted prisoners as cases of prison insanity, and, accordingly, they have been excluded this year from the insanity statistics. The remaining 164 cases were convicted and sentenced; of these, 121 were found insane on reception and 43 subsequently. It appears from this that many persons are convicted and sent to prison, their insanity being either ignored or undetected at their trial.

In the convict establishments fifteen prisoners were certified insane and removed to asylums. There were no suicides. The death-rate was 9·7 per 1000. An important feature, from a medical point of view, was the decision of the directors to send all weak-minded prisoners, or any showing a tendency to mental deterioration, to Parkhurst Prison. The scheme seems to be working well; they are under special supervision and are employed at labour suited to their physical and mental condition. On their release efforts will be made to assist them and give them a helping hand. This is a wise, humane, and judicious decision, for such men frequently find their way into prison. On account of their mental infirmity they are unable to obtain suitable occupation, and in the stress and hurry of the busy world they are cast aside, and, almost of necessity, have recourse to acts of an anti-social nature. The prevention of crime and the treatment of criminals are important and far-reaching questions which are being made the subject of inquiry and investigation by many able workers, both in this country and abroad, and it is pleasing to note that the Prison Commissioners are addressing themselves to the work in a scientific and progressive spirit.

Annotations.

"Ne quid nimis."

EASTBOURNE AND VACCINATION.

THE curious muddle into which the Eastbourne guardians have got with regard to vaccination affords another illustration of the need for immediate legislation on the subject. Some months ago a vaccination officer was advertised for and appointed. It seems that he had been told by the board that he would be supported in doing his duty. Having prepared a list of defaulters he wrote to ask for instructions, and the committee before whom the request was laid resolved "that further consideration of the letter be deferred for two months." A local newspaper reports that at the guardians' meeting the Rev. J. W. Parrington said the board had repeatedly stultified itself by refraining from carrying out resolutions which it had arrived at to enforce the Vaccination Act, and he opposed any further stultification. At the same time the vaccination officer was understood to be likely to take legal proceedings against the guardians if they failed to support him in carrying out the Act. On the other side it was urged by Mr. Luck that although the vaccination officer "was appointed to do the work the board had no right to enforce the law; it was optional." He also made the remarkable assertion "that the Royal Commission unanimously decided that prosecutions should be discontinued," and when a statement of this sort was called in question by the clergyman who had previously spoken, Mr. Luck's retort courteous was that when Mr. Parrington understood what he was talking about he would listen to him. Mr. Luck himself

Digitized by Google

seems quite unable to understand the difference between prosecutions and repeated prosecutions. He further intimated to the guardians that the Local Government Board were all medical men and pecuniarily interested in vaccination. Moreover, he himself had nailed his colours to the mast, and Jenner had got £30,000, and the death-rate of Eastbourne was the lowest on record, "and why," he asked, "not let well alone?" After all this valuable information and cogent reasoning, the determination to defer the matter for two months was carried by nine votes to seven, though to an outsider it is not clear why this should be described as a "victory of anti-vaccinators." The underlying feeling appears to have been that Eastbourne cannot afford to let the truth be known about its neglect of vaccination, and that, at least, the summer visitors might be allowed to depart before prosecutions were begun. This is a dangerous policy. The longer the neglect the worse may be the punishment. Gloucester, like Eastbourne, purported to trust to sanitation. Mr. George Newman, secretary to the Gloucester Anti-vaccination Society, declared to the Royal Commission that Gloucester was a very sanitary town, one of the public bodies in the town also professed to the Commission its trust in sanitation, and a book was written to show how little vaccination there was in Gloucester, and how little small-pox. Then came Nemesis under the guise of small-pox, and at once the tune was changed. Gloucester was no longer sanitary but highly insanitary, and that cry has been kept up ever since. He is happily wise who is wise by the experience of others, but Eastbourne refuses to be wise. The schoolmaster small-pox is likely to have no lack of pupils when the time comes, and as in the past, the children, alas, will have to pay the penalty of death or disfigurement for the folly of their parents.

ATTENDANCE AND DEATH CERTIFICATION BY DRUGGISTS.

AN inquest at Redruth, held by Mr. E. L. Carlyon in reference to the death of Florence Mary, daughter of Elizabeth Watling, discloses a state of matters as regards the medical care of children, and the ease with which registrars and sextons are satisfied that cannot too seriously or too soon engage the attention of the Registrar-General and the Home Secretary. Mrs. Watling had had thirteen children. A midwife, Mrs. Tirrell, not a certificated nurse, had attended her on five occasions. The present child, born on July 27th, was a fine child at birth. On one occasion the child was still-born and she gave a certificate in the following terms: "I hear by Sertifey that Mrs. Watling was confined of a still born mall child. Susen tirrel." She took the body and the certificate to Mr. Trevena, sexton at Treleigh. She had been a midwife thirty-five years and it had been her custom to give certificates like that. She did not think she had attended more than ten such cases, which she disposed of as follows: She had "given" seven to Mr. Remfry, Redruth parish church sexton, and two had gone to Mr. Henry Peters at the East-end Cemetery. "She had permission from Major Hayes, a magistrate, to give such certificates." A druggist, whom the mother called "Dr. Rowe," had always attended her (Mrs. Watling's) babies—that is, if they required more attendance than that of the midwife. She gave a list of three cases so attended by "Dr. Rowe,' and said that he gave certificates. In the present case he suggested that she should call in Dr. Laurie, but she did not, for "Dr. Rowe" had always attended her babies, and he did not say he was not qualified to attend or to give a certificate. The day after suggesting that Dr. Laurie should be called Mr. Rowe sent another medicine and justified his doing so on the ground of humanity. When the child died he gave a certificate—or, as he preferred to call it, a statement—of death from diarrhœa. Medical evidence was given by Dr. Permewan, who had made a post-mortem examination and found death to be due to diarrhœa. He disapproved of the diet of the child—boiled bread and baked flour and milk. One of the medicines supplied by the druggist was syrup of poppies. In his opinion this implied want of medical knowledge, and he would have blamed himself for ordering it for a child of that age unless he had seen the child and assured himself that the lungs were clear. The coroner spoke in terms not too severe of Mr. Rowe. He spoke of him as a "positive danger to society," though he had been twice warned, and once proceeded against, by the Apothecaries' Society. The jury, some of whom appeared to sympathise with Mr. Rowe, found that the child died naturally. The *Daily Mercury* and the *Western Morning News* show by their full reports their sense of the significance of the facts—we may say, the system—which the coroner has here exposed. But the responsibility rests elsewhere.

SALT IN THE NAVY.

THAT it is only within the last few days that the Admiralty have sanctioned the use of salt in the bluejacket's daily allowance of food will come as a surprise to not a few. Hitherto if the sailor required salt he had to purchase it. It was practically the only condiment omitted from the ordinary cruet list, and the reason of this omission until quite lately is not far to seek. In the old days of wooden ships Jack's diet consisted largely of salted meats, and salt on the table would have been an obvious, and most probably an irritating, superfluity. But owing largely to the increased facilities and improvements in the machinery for preserving meats without the use of salt or added substances at all, as well also to the fact that our modern warships are seldom many days' steam from port, "salt horse" has, greatly to the increased comfort and well-being of our sailors, practically become a thing of the past—at any rate, as an exclusive article of diet. Salt is now, therefore, a necessity wherewith not only to season food, but, as experiments have shown, to assist very materially in its assimilation. As is well known, salt promotes the diffusion of fluids through the membranes, and it very distinctly increases the solubility of certain nutrient substances. It has been said that the entire withdrawal of common salt from food would be fatal, an absolutely saltless diet speedily leading to albuminuria. This concession, therefore, is of the utmost importance, and it is a matter of surprise that the Admiralty have been so tardy in granting it.

SYPHILIS TREATED WITH COLEY'S MIXED TOXINS.

DR. C. S. EVANS and Dr. C. M. Paul have published in the annual report of the Cincinnati Hospital a series of fifteen cases of syphilis treated with Coley's mixed toxins, the patients' symptoms including such varied manifestations as primary chancre, secondary eruptions, broken and unbroken gummata, and condylomata lata. The treatment was in each instance commenced with the minimum dose of two minims, diluted with an equal quantity of water and injected deeply in the muscles of the buttock with an ordinary hypodermic syringe; the side was alternated each time because of the soreness caused; the injection was given every other day, and as a rule the dose was increased at each injection. The maximum dose given was fourteen minims, and it was noticeable that this dose could be continued day after day without any more disturbance than followed the initial dose of two minims. As a rule, some pain followed the injections, but this lasted only a short time and was succeeded by a soreness which persisted for two or three days, but was never so severe as to compel the

Digitized by Google

patient to remain in bed. The most pronounced symptom following the injections was malaise, which was felt very quickly, and, as a rule, was peculiarly depressing, but disappeared in a few hours. Headache, diarrhœa, high temperature, and pains in the bones were also met with, but there was no formation of abscesses in connexion with any of the 237 injections which were given, and apart from the symptoms above noted there were no unpleasant after-effects, a thing which cannot be said of mercury. Two of the fifteen patients were treated with mercurial inunction and one with iodide of potassium before the toxin was administered. The remaining twelve were treated with toxin only. The duration of the disease in these cases was respectively five months, seven years and a half, three months and a half, two months, four months and a half, five years, four months, four months, perhaps nine weeks, six months, seven months, and five months. The duration of the toxin treatment in the cases taken in the same order was respectively twenty days, two months, twenty-seven days, thirty-nine days, fifty-seven days, thirty-two days, thirty-five days, thirty-nine days, twenty-seven days, thirteen days, twenty-one days, and twenty-one days. Ten of the twelve patients had ulcerated chancres eight of which were entirely healed and two were almost healed at the end of the treatment. In every case the eruption disappeared, the mucous patches healed, the enlarged glands became smaller, and the patient gained flesh and strength. In conclusion, however, Dr. Evans remarks that the worth of toxin is as yet mere conjecture, and that absolutely nothing can be said as to the ultimate results.

MODERN ALCHEMY.

THE sea-serpent story is beaten. Silver has been transmuted into gold by the simplest possible process, and this at a time when currency is a most vexed question, in which America more than any other country is interested. It is not, therefore, a matter of intense surprise that the transmutation has been effected by an American investigator. He has converted Mexican dollars (why did he not start with pure silver?) into an ingot consisting of a mixture of gold and silver more than nine-tenths "fine," from three-fifths to two-thirds of the precious metal being found to consist of pure gold. Mexican dollars, by the way, contain also copper. All that is required for this transmutation is extreme mechanical pressure. There can be no doubt of America's capacity to supply an abundance of this commodity. Pressure acts, doubtless, upon the silver atoms and gives them a greater density, so that from 108 the atomic weight shoots up to 196. That is, starting with a white metal—namely, silver—of a specific gravity of 10, the effect of an enormous pressure is to increase this gravity by about double (the specific gravity of gold is 19·5), the resulting mass changing colour—presenting, in fact, all the appearance as well as the properties of the noble yellow metal. Bimetallism is doomed and America's financial superiority as a nation amongst nations ensured.

THE MANCHESTER CORPORATION AND CARRINGTON MOSS.

THIS estate, of 1100 acres, was bought for a sum of £38,000, by the Manchester Corporation in 1886, to make provision for the disposal of refuse and other matter from the closet system of the southern part of the city. The greater portion was wild boggy moss-land which yielded annually a few brace of grouse. A sum of £80,000 was laid out for light railways, roads, drainage, rolling stock for the railway, buildings, and other necessary works. An estimate prepared by the city surveyor places the present value of the property at some £12,000 higher than its cost to the city. "The whole moss has, in fact, been developed into highly cultivated farm and garden land." Refuse, chiefly nightsoil, is taken daily by the Ship canal to a wharf conveniently near, lifted from the barges into tanks and taken to various points for distribution over the ground. The Cleansing Committee farm about 400 acres and the remainder is let off to tenants, who are supplied with manure. Since 1890 more than 425,000 tons of collected matter have been distributed over the moss, and by this time the power of absorption by the soil has necessarily somewhat diminished. In future twenty tons of manure per acre will be supplied annually, and the surplus will be taken to Chat Moss, which was recently purchased. At the outset the bog land was thoroughly drained, and, notwithstanding the constant additions of top dressing, there is still a well-defined sinking of the land. In face of the general agricultural depression it is a novelty to learn that "a considerable profit has for some years been made on the working of the farm." Not far from the homestead seventy acres are in charge of the Parks' Committee, where golden elders, acres of rhododendrons, with other shrubs and trees, together with flowers in abundance, are grown for use in the parks and for the decoration of the city squares. These results of the "dry method" are not attainable under the water-closet system which culminates in the scheme for a culvert sixteen miles long, to cost before it is done probably £300,000, in order to provide for the waste of hundreds of thousands of tons of matters having manurial value.

THE LATE DR. WILLIAM GARDNER.

A SURVEY of the progress of medicine and surgery in Australia shows that the present advanced state of devel p-ment is due to the talents and industry of a number of workers, among whom the late Dr. William Gardner deserves honourable mention. Although the greater part of his life was passed in Australia he was not of colonial extraction, having been born in Birkenhead, Cheshire, in November, 1846 He went with his parents to South Australia in 1850, received his early education in Adelaide, and was subsequently employed for some years in the English and Scottish Bank in that city. Having then made up his mind to enter the medical profession he spent the years 1870, 1871, and 1872 at Melbourne University. He then returned to this country and entered at Glasgow University, where he took honours in most of the classes and graduated as M.B., C.M., with first-class honours, in 1874. Immediately after graduating he went back to Australia, and held resident appointments at the Adelaide Hospital from 1875 to 1877. In 1876 he took the degree of M.D. at Glasgow University, his thesis, which was on Hydatid Disease, being awarded commendation and a gold medal. From 1879 to 1891 he was surgeon to in-patients at the Adelaide Hospital. In 1883 he was elected President of the South Australian Branch of the British Medical Association; in 1887 he was appointed lecturer on surgery at the Adelaide University; in 1889 he was instructed by the Government of South Australia to prepare a report on hospitals in India, and the substance of it was published in the *Australian Medical Journal* during 1890. He spent the year 1891 in Europe, and on returning to Australia in the beginning of 1892 he settled in Melbourne, where he was appointed honorary surgeon to the Hospital for Sick Children in 1893, and founded the *Intercolonial Quarterly Journal of Medicine and Surgery* in 1894. At the Intercolonial Medical Congress, held in 1892, he was President of the Section of Surgery. In the midst of his scientific and literary activity, to which was added the responsibility of a busy practice, his health began to give way, and in the end of 1895 he had a severe cerebral seizure, after which it was found that he suffered from considerable arterial degeneration and cardiac

Digitized by Google

hypertrophy. He spent most of 1896 travelling in Europe, and about March of the present year he commenced his homeward journey to Melbourne, where his friends expected him to arrive about the middle of April, but to their profound grief he died at Naples. Dr. Gardner's contributions to medical and surgical literature were valuable and very numerous; his favourite subject was the treatment of hydatid disease, for which he adopted Lindemann's operation, and proved its advantages by a series of successful cases.

THE DISPOSAL OF IMPORTED BAD EGGS.

BY some remarkable oversight the Port Sanitary Authorities permitted a cargo of bad eggs to be brought above Gravesend because it was thought that possibly a few good ones might be saved. The proportion of good ones subsequently picked out did not appear, but no less than 472 cases, each containing 1800 eggs, were landed at Limehouse and destroyed. It so happened that during this process an inquest was being held in the neighbourhood, and both the jury and coroner were disgusted, naturally enough, at the foul smell which had intruded into the coroner's court. So nauseating was the stench that several witnesses were taken ill with retching and vomiting. The Port Sanitary Authorities are much to be blamed in this matter for allowing the malodorous cargo to be landed at all, and, worse still, for countenancing the disposal of the eggs in this stupid and clumsy fashion, for it appears that the eggs were disposed of by first smashing them upon the pavement and then washing the resulting product down the drain with disinfectants. Somebody should have been compelled to pay the expenses of putting the ship out to sea again there to leave the loathsome cargo to the purifying and deodorising action of the ocean.

THE DANISH BUTTER INDUSTRY.

WE received recently a copy of an article in *brochure* form, entitled "A Land flowing with Milk and Butter: the Truth about Danish Dairying," &c. The article was written by Mr. D. Young, the editor of the *North British Agriculturalist* from which paper it was reprinted. It is a very grave attack upon the sanitary conditions of the Danish dairies. It purports to show an abnormal prevalence of tuberculosis amongst the cattle there owing to overcrowding and the neglect to ensure efficient drainage. "There can be no question, therefore," the article concludes, "that the extreme prevalence of this disease in Denmark is due primarily to the unsanitary conditions under which the animals are kept, and the ravages of this dire disease, which is communicable from animal to man, is (*sic*) not only one cause of the high death-rate of that country, but is also a serious source of loss to the dairy farmers in that 'land flowing with milk and butter.'" The importation from Denmark into this country of dairy produce is, as is well known, an important business, and if the state of things in Denmark has been correctly described by Mr. Young it is obvious that some steps should be taken to prevent the introduction of a probable source of insidious disease into this country by this means. The connexion between milk and tuberculosis has been well established, and we believe excellent progress is being made in this country towards providing efficient and sanitary accommodation for cows, in short, of placing them under the best possible surroundings which will eradicate the disease. Mr. Young's serious statements have not gone unchallenged. Indeed, they are categorically denied in a letter in the *Times* of Sept. 3rd by Mr. Harald Faber, Commissioner to the Danish Government. Mr. Faber quotes the following paragraph occurring in the final report of the Royal Commission on Agriculture: "It is clear from evidence before us that in some cases the buildings used for cows and the surroundings are in an unclean and insanitary condition, and that insufficient care is taken to keep the dairies perfectly clean. In the coöperative dairies in Denmark cleanliness is enforced by stringent regulations to ensure the supply of sweet, pure milk, and to prevent the spread of infectious disease by dairy products." We do not doubt, however, but that this portion of the subject has been fully inquired into by the Royal Commission on Tuberculosis, and, as their report is not yet issued, it is expedient, we think, in the interests of the public, that a preliminary announcement should be made by the Government to set a very serious indictment at rest.

THE LANDING-PLACE AT BRINDISI.

ACCORDING to a contemporary, certain proposals for altering the berthing-place of the Peninsular and Oriental Company's steamers at Brindisi are not likely to meet with general acceptance. The site chosen by the Public Works Department for a new landing quay is, it is said, doubly objectionable—firstly, as being so exposed to south-west winds as to make the manœuvring of these large vessels at times a matter of difficulty and danger, and, secondly, because at this point the town sewage, with a strange disregard to the public health, is carted into a shallow part of the harbour. The latter objection is obviously an important one in view of the fact that several hundreds of passengers would thus on each voyage be exposed to the danger of conspicuous insanitation. Another plan provides for an extension of the existing railway line and leaves the mooring station of the large steamers in its present situation. We are not informed as to the cost of these alternative proposals. It is estimated, however, that the yearly outlay in connexion with the Peninsular and Oriental Company's traffic in Brindisi is from £40,000 to £50,000, and that in the event of the first-mentioned suggestion being carried out this traffic is in danger of being transferred to Marseilles. The Italian Government, we understand, has not yet given its decision on the subject which evidently calls for reconsideration.

THE TREATMENT OF STRABISMUS.

IN the *New York Medical Journal* of July 24th, 1897, Dr. Prentice describes a new method of treating strabismus, which, however, he appears to have used only in cases of the internal strabismus which accompanies hypermetropia. His idea is to forcibly repress spasm of the ciliary muscles and the associated action of the internal recti by over-correction with strong plus lenses. In an ordinary case of internal strabismus, if a pair of plus 5 or 6 D be used, the strabismus will be seen at once to materially diminish. He also uses prisms to still further repress the action of the internal recti. The following case will make his method plain. A woman, aged twenty-five years, had convergence of about five millimetres. The vision of the left eye was normal, of the right $\frac{2}{3}$. After using atropine ·75 D of hypermetropia was found. Plus 5 D glasses were given for reading, and she was directed to hold the book at the farthest distance that she could read, and to read as long and as frequently as possible. For distant vision plus 2 D glasses were ordered, which gave but $\frac{2}{3}$ of vision. In two weeks there was sufficient relaxation of the internal recti to admit of fusion of objects at twelve inches through the plus 5 D glasses. Three days later 8° of prism with base in were added to the reading-glasses, and the fusion was still maintained. From this time as much prism was from time to time added as could be fused for, thus producing a constant effort of the internal recti to relax their spasm. At the end of two months 24° of prism combined with plus D 5

Digitized by Google

spherical were used for reading. Also she could fuse at 12 feet with the plus 2 D or distance glasses, which now gave vision $\frac{12}{18}$. In three months fusion was possible at all points with 4° of prism. A month later the patient could fuse for 8° of prism with the 2 D glasses, which now gave vision $\frac{12}{18}$ instead of $\frac{12}{18}$. Vision was now normal in both eyes with plus 1·50 D The writer concludes that this repression had further relaxed the ciliary muscle and revealed ·75 D more hypermetropia than the atropine had. In six months vision through the 2 D lenses was $\frac{12}{18}$, and their continuance was advised, with the occasional use of the sphero-prisms for reading.

A TERROR-STRICKEN PATIENT.

A SAD story was revealed a few days ago by a woman who applied to a magistrate for assistance in finding her daughter who had suddenly run away. It appears that the girl, who was sixteen and a half years old, had recently been attending a hospital for some illness, and from what was said she thought that an operation was necessary in order that she might regain her health. On leaving the hospital she was told to return again next the day, but instead of doing so she left her situation and disappeared. What the nature of the proposed operation was we do not know, but at any rate the thoughts of it so preyed upon the girl's mind that she ran away from all her friends, and in a letter to her mother she stated her determination to walk on until she found some place where she could die. It can only be hoped that she will soon be found, and that calm reasoning will allay her fears, or at any rate convince her that, whether the operation be necessary or not, the decision of having it done rests entirely with herself. It is easy to imagine that a young girl of neurotic temperament might work her mind into such a state that she would rather run away than face the dreaded ordeal, but fortunately the nerves of the majority are sufficiently strong to bear these unpleasant shocks. Children are especially apt to be easily frightened, and when they go to the hospitals they should always be accompanied by some grown-up person and not, as frequently happens, sent by themselves or in company with other children. By themselves they are often incapable of explaining their own symptoms and also of understanding any directions for treatment which it may be necessary to give them.

HOW DO CLIMATIC INFLUENCES PREVENT THE PROPAGATION OF PHTHISIS?

DR. GARDINER, of Colorado Springs, discusses this subject in the *Boston Medical and Surgical Journal* of July 22nd, 1897. He very reasonably insists that the impression that phthisis is not communicated in the arid or elevated regions of the world is not at all proved by the statistics generally brought forward. The immunising power apparently possessed by a climate may be really due to the manner of life, such as isolation and the like, day and night in the open air, or to the selection of lives, as the early settlers are necessarily strong. It is therefore only after a country has been settled for some time that indoor industries, overcrowding, and the general insanitary surroundings of civilisation exert their full action. Such conditions, however, now exist, as the dry and elevated regions of almost the entire world have populous cities, whose inhabitants lead indoor lives comparable to those of the dwellers in the crowded civilised centres from which our statistics have for years been drawn. The statistics of these cities clearly show that the prevailing opinion as to the influence of climate is well founded. For example, Denver has a population of 150,000, tall buildings which shut out the light, industrial occupations which are conducive to phthisis, and a large proportion of phthisical invalids scattered amongst its inhabitants. Yet only 64 deaths from non-imported phthisis occurred in 1896. The average city would show 450. Again, circular letters were sent to medical men practising in the dry belt which comprises Utah, Arizona, Wyoming, New Mexico, and Colorado, asking the number of cases seen or heard of by them and the number of years each had been in practice; 203 years of observation in practice gave only 130 cases of non-imported phthisis, fully 80 per cent. of which were from Salt Lake City, in native Mexicans in New Mexico, or in an altitude below 3000 ft. The writer attributes the climatic influence to the loss of virulence of the tubercle bacilli when distributed in the form of dust, from exposure to the constant sunshine in the rarified air, and also to the increased depth of respiration which high altitudes produce.

A NEW CORSET.

"MADGE," the editress of "Girls' Gossip" in *Truth*, who may always be depended on to take a sound view of the fashionable fads and fancies of the day, writes as follows in a recent issue of Mr. Labouchere's journal: "A new corset, devised by someone who has little sympathy for flesh and blood, is to transform the ordinary figure into one that measures 20 inches round the waist, 40 round the chest, and 48 or 50 round the hips. Please note this last item in the new development. In the illustration accompanying these particulars the hips rise in a semicircle at either side of the waist. It is a hideous distortion, and I should think it must be some sort of a joke, though letters from artists, physicians, society women, and fashionable dressmakers are printed on the subject. We shall see." The notion, it seems, hails from America, but we very much doubt its ever coming into vogue, either in the new world or in the old. A wasp-like waist is not a thing of beauty in the human species, to say nothing of its physiological inappropriateness. We quite agree with "Madge's" concluding remarks on the subject: "The proper measurements of a woman whose height is 5ft. 7in. are 26 inches round the waist, 34 round the chest, and 40 about the hips. Compare these figures with those I have given above!"

FORCIBLE REDUCTION OF POTT'S CURVATURE.

ONE of the most striking of the recent advances of surgery has been the introduction of the forcible method of reducing the deformity in Pott's curvature of the spine. Though attempts have been made from time to time to diminish the projection of the spinous processes of the affected vertebræ, yet the teaching recognised by practically all surgeons up to almost the present moment has been that no attempt should be made to reduce forcibly the curvature, and that all the surgeon's efforts should be directed to obtain consolidation and thus prevent the increase of the deformity. To Chipault, of Paris, and to Calot, of Berck-sur-Mer, must be accorded the credit of first having successfully employed forcible reduction. Since the publication of the results obtained by these surgeons numerous other papers on the subject have appeared. In many of the earlier cases it was thought necessary to resect the spinous processes of the vertebræ of the diseased area. A very interesting paper was read on this subject at the Moscow Congress by Professor T. Jonnesco, of Bucharest. He performs Calot's operation with certain modifications. In the first place, he never finds it necessary to remove any of the spines; and, secondly, he employs pulleys to obtain the extension. Manual traction is irregular and jerky, and is liable to be unnecessarily strong. The method employed is as follows. The patient, anæsthetised, is placed face downwards on two padded supports, one under the thorax and the other under the pelvis; a sling like that used in suspending a patient when a Sayre's jacket is put on is placed

Digitized by Google

beneath the chin and occiput, and a somewhat similar one is fastened round the pelvis, so that longitudinal traction can be made readily. The head sling is attached to the wall, and to the pelvic band is fastened a compound pulley, a dynamometer being interposed. Traction is then made until the dynamometer registers 45 or 50 kilogrammes. Two assistants then fix the pelvis and support the lumbar spine, while the operator presses firmly on the projection. A cracking sound is heard and the prominence disappears. Then a plaster-of-Paris jacket is put on, surrounding the whole trunk and fixing the head. The cases operated on were thirteen in number, and the ages varied from two and a half years to twenty-two years. In most case excellent results were obtained. Three deaths occurred—one patient died under chloroform, another died a week later from broncho-pneumonia, and the third died two days after the operation, but as no post-mortem examination was made no cause could be assigned for the death. As might be expected, recent and slight cases are considered the most suitable for operation, but even severe and long-standing curvatures have been treated with success.

SUPPER-BEER IN SCHOOLS.

WE have received, as might be expected, several communications on the important, if unsavoury, subject brought to the notice of our readers last week by the former head-master of Foyle College, Londonderry. Among these came a temperance leaflet on the impropriety of certain uses of alcohol in schools, written by Dr. Clement Dukes, physician to Rugby school, the teaching of which is so sensible and simple that we desire to recapitulate it. After announcing, *in limine*, that in his opinion no alcohol whatever should at any time be given to the young of either sex save as a remedy in disease, Dr. Dukes made more particular remarks with regard to the domestic management of our big public schools in condemnation of "the cruel and pernicious practice which prevails at most of them of supplying supper at 9 P.M. consisting of various stimulating articles of food, from meat and tarts to cheese and beer." We are not aware how far it is the case that supper of such a character is placed before the boys at most of our public schools—possibly Dr. Dukes's words were spoken when such heavy and ignorant feeding of small boys was more usual both at home and at school — but we are prepared to endorse to the full his views on the mischief that such food might well work if given to growing lads just before the night's rest. Boys do not require the hypnotic influences of beer—most of them find Thucydides or conic sections, Nepos or Xenophon, football or rackets, to fulfil all their soporific needs—while the stimulus given by beer to the animal passions is most dangerous at a late hour in the evening, when no exercise of mind or body will follow to counterbalance the excitation. It cannot be too widely known that to give boys, as a rule, suppers of an indigestible or stimulating character immediately before sending them to bed is to do them a cruel wrong. It is to double their difficulty and to deprive them of their safe-guard, and although the facts hold good in home life as much as in school life, it is, of course, at school that the consequences are most apparent and most disastrous.

CATHETERISM OF THE URETERS IN THE MALE.

IN the *Journal of Cutaneous and Genito-Urinary Diseases*, June, 1897, is published an account of this important innovation, which Dr. Meyer brought before the New York Academy of Medicine. It constitutes an extension to the male of methods devised by Dr. Howard Kelly in the case of the female. The following is the mode of procedure. The bladder is washed out and cocainised and from five to seven ounces of clear fluid are introduced. The ureter cysto-scope containing the ureter catheter is then passed. After the interior of the bladder has been inspected and the ureteral openings have come into view one of them is approached and the catheter is pushed forward. The catheter is not allowed to pass more than two inches into the ureter, and the wire mandrel is withdrawn. As a rule the urine will begin to flow drop by drop. The writer avers that if his directions are properly followed there ought to be no difficulty in skilled hands performing the operation. In only one case did he fail, and here there was evidently congenital contraction of the mouth of the ureter. In the discussion which followed there was a consensus of opinion that the operation was by no means so easy as Dr. Meyer considered. Also it was pointed out that the introduction of the catheter might produce sympathetic anuria in the only working kidney. The value of the operation, especially in cases where nephrectomy is proposed, is obvious.

LEPROSY IN GREAT BRITAIN AND IRELAND.

WE are asked to announce that the authorities of the forthcoming International Leprosy Conference are anxious to obtain particulars of any cases of true leprosy which have come under medical observation during the last ten years or so in Great Britain and Ireland. Members of the profession who may have knowledge of such cases will confer a great favour and will materially assist the inquiry by communicating with Dr. Phineas S. Abraham, 2, Henrietta-street, Cavendish-square, who is secretary to the Leprosy Investigation Committee (National Leprosy Fund). What is asked for is information in the form of a short note giving initials of patient, sex, age, nationality, variety of the disease, length of time affected, in what country acquired, &c. Any facts, negative or positive, which may be supplied will be duly acknowledged at the conference.

THE RISING OF THE BORDER TRIBES.

THE latest news from India is much more satisfactory. There is a lull on the frontier at present. The main elements of a satisfactory kind in the recent intelligence are that the Afridis are beginning to count the probable cost of their action, to be less attentive to the preachings of the Mullahs, and to feel the loss of their subsidies and trade with India, as well as to be alarmed at the prospect of punitive expeditions against them; that the Mohmands are not disposed to rise; and that the Ameer of Afghanistan has not only spoken out, but taken some effective steps to punish those of his subjects disposed to join in the outbreak against British authority. It is the grave financial loss in which the Indian Government will be involved in suppressing a general revolt of the border tribes rather than any actual danger to our Indian rule—for that is comparatively small—that is so embarrassing at the present time. The policy seems to be to deal as promptly as practicable with those of the tribes who have already taken part in the revolt, and once having shown our power and determination to deal with them and compel their submission, to be ready to act in a friendly way to them when it has been obtained. Several punitive expeditions will soon be ready to start on their work, but we may be sure that the Government of India will only be too ready to bring things to as speedy an end as possible. The lesson that is required is the manifestation of our power to deal out rewards as well as punishments. There will be much temporary sickness, no doubt, but the news is not, so far, unfavourable in this respect. The adequate supply of animal transport has always been a difficulty in our military expeditions. We have no doubt that the field medical service system will prove to be good, but it will, we fear, be hampered by the fact that the medical departments of India are shorthanded at the present

Digitized by Google

time. The feeding and clothing of the expeditions will be a source of some difficulty; the insufficient supplies of clothing for the native followers and the soldiers of the native army engaged in frontier warfare are a fruitful source of inefficiency and of sickness, especially of a pulmonary kind. The natives of the plains of India, as might be expected, stand cold and exposure very badly, and, especially those who have previously suffered from malaria, frequently die from pneumonia.

LARYNGEAL PERICHONDRITIS AS A COMPLICATION OF TYPHOID FEVER.

LARYNGEAL perichondritis is one of the rarer complications of typhoid fever. In the *Journal of the American Medical Association* Dr. M. H. Fussell records the following case. A man, aged thirty years, had an unusually severe attack of typhoid fever. From the beginning there was much hoarseness. In five weeks the temperature fell to normal. Six days afterwards he ate an apple. Almost immediately he was seized with a severe attack of coughing and the signs of laryngeal stenosis. On the third day after this he was suffering extremely from the stenosis of the larynx and begged for relief. Examination of the larynx showed œdema and no ulcerations. Externally the region of the thyroid cartilage was swollen and extremely tender. Tracheotomy was refused. Two days later the œdema of the larynx had largely disappeared, but the stenosis was as great as before. The laryngoscope showed a pale mucous membrane and a decided narrowing below the cords. The patient died on the seventh day. The usual signs of typhoid fever were found at the necropsy. The interior of the larynx was filled with frothy muco-purulent matter. There was no ulceration of the cords. Section through the posterior angle of the thyroid cartilage, which was necrosed, showed a large perichondrial abscess.

PHARMACY AND THE SALE OF POISONS IN THE ISLAND OF JERSEY.

THE dangers attending the indiscriminate sale of poisons have only recently been recognised by the Legislatures of the Channel Islands, but it is satisfactory to find that two of them have at length made adequate provision for the safety of the public. As is well known, these islands legislate for themselves through the "States," which are the local parliaments, and are quite separate for each island. Guernsey passed a Pharmacy Act in 1882, but in the neighbouring island of Jersey there was no Pharmacy Act and no control whatever over the sale of poisons until Aug. 5th, 1897, on which date the State passed a Bill on the subject, introduced in February, 1896, by Dr. W. Duret Aubin, Deputy in the States for St. Heliers. The Act, or Règlement as it is called, will be in force for three years; it is in the French language, and consists of seventeen articles. It prohibits the practice of pharmacy in Jersey except by permission of the Royal Court, and provides that in future this permission shall be granted only to those who are duly recognised either (1) as "pharmaceutical chemists" or "chemists and druggists" by the Pharmaceutical Society of Great Britain; or (2) as "pharmaceutical chemists" or "chemists and druggists" by the Pharmaceutical Society of Ireland; or (3) as "Pharmacien de Première Classe" or "Pharmacien de Seconde Classe" by one of the Schools of Pharmacy of the University of France. The poison schedule, Parts I. and II., as well as the regulations with regard to the recording of the sale, are practically identical with those which are in force in England, with, however, the important addition that carbolic acid is included in Part II. Carbolic acid is so frequently intentionally swallowed as a means of suicide, and so many accidental poisonings have occurred in connexion with its use as a domestic disinfectant, that we are glad to find that the States of Jersey have set the example of prohibiting its indiscriminate sale, the urgent need of legislation on the subject being apparent from the fact that the Registrar-General's returns for 1895 show that in England and Wales during that year 580 persons committed suicide by poison, of whom 224 resorted to carbolic acid. The Jersey Act makes no reference to the addition of soot or indigo to arsenic, an admixture which is authorised in England.

INQUEST ON A CENTENARIAN.

To hold an inquest on a centenarian is as novel as it is rare, but with the law as it stands the inquiry into the death of Mrs. Mary Neighbour, at Ashurst Wood, Forest Row, Sussex, on Sept. 7th, was a matter of compulsion, the direct cause of death being the result of a fall. The old lady, who was but three months short of her 101st birthday, resided in a humble cottage with a grand-daughter. After taking her tea on Aug. 30th, in the temporary absence of the grand-daughter, the old lady got up from her chair. No one saw what happened, but from the fact that the chair recently occupied by the grand-daughter had been thrown over it was thought that she rested her body with her hand on the chair, which, not being evenly balanced, fell over, throwing the centenarian violently to the ground, her head striking the fender. A sudden and unexpected shock of this kind was quite sufficient to bring about her end somewhat sooner than would otherwise have been the case, for, as was only naturally anticipated, medical evidence showed that deceased was suffering from marked senile decay. She was unconscious when picked up from the floor, and she remained in this condition till the following Sunday afternoon. Her children (four by her first husband and seven by her second) and their descendents number 303, of whom some 200 are still living.

THE INFANT LIFE PROTECTION ACT.

THE amended Infant Life Protection Act, which is to become operative on Jan. 1st, 1898, may be accorded a qualified welcome as providing for the more practical application of a measure which has hitherto stood much in need of improvement in this respect. In the new Act considerable care has been taken to ensure the notification and periodic inspection of nurse children, the respectability of their nurses, and the sanitary condition of their surroundings. Excellent as these provisions are, however, their value is materially diminished by defects in the Act which must very seriously limit its utility. One of these consists in the exclusion of single nurse children from the Act, the other in the exemption of children for whose maintenance a sum exceeding £20 has been paid. The effect of these omissions is obvious. They virtually describe the Act as intended merely to suppress the unregistered crêche, while it leaves untouched the system of putting out to nurse which is at the root of much infant mortality. The unregistered crêche if broken up into its constituent units may still continue to flourish unobserved by the eye of authority. The nursed offspring of a wealthy parent may, under any conditions, escape supervision. The probable effect of these important omissions is obvious. Nurse children, it is well known, are usually illegitimate. They are, as a rule, not desired by their parents. If they should be committed to the keeping of unscrupulous persons one by one, or with a substantial payment, the law is no longer responsible for their safety which must therefore be at best an unknown quantity. We yield to none in appreciation of every honest endeavour to promote the welfare of children. For this reason we willingly acknowledge such advantages as

Digitized by Google

the amended Act confers on them. For this reason also we must admit a keen sense of disappointment that the omissions we have referred to have so greatly stultified its intention as to make it practically unreliable for the protection of infant life.

THE NEW INFIRMARY AT NEWCASTLE: A MAGNIFICENT PIECE OF MUNIFICENCE.

SOME two or three months ago we chronicled the interesting fact that Mr. Riley Lord, J.P., had been able to raise £100,000 for the re-building of the Royal Infirmary at Newcastle, of which ancient city he is an ex-mayor. The energy and perseverence that were displayed by Mr. Lord in raising this very large sum—probably the greatest effort in commemoration of the Diamond Jubilee that was accomplished outside the metropolis—have now been emulated by the magnificent generosity of another Newcastle citizen, Mr. John Hall, who has given out of his private purse a similar sum for the same purpose. With £200,000 to spend the city of Newcastle ought soon to have a magnificent infirmary, and as only reasonable conditions are attached to Mr. Hall's splendid donation, which was formally accepted by the Governors of the charity last week, we may expect soon to hear that a site has been selected and a plan approved of. The competing architects have been told of the altered conditions under which their designs may now be constructed, and the time for submitting the plans to the building committee has been extended.

SIMPLE MYOSITIS AS AN OCCUPATION DISEASE.

IN the *International Medical Magazine* of Philadelphia, July, 1897, Dr. Harold N. Moyer publishes the following exceptional case. A wood carver, aged forty-one years, in excellent health, noticed a painful condition on the outer side of the right elbow-joint. It gradually became worse, and soon a swelling was observed, but there was no redness of the skin. A few days' rest would reduce the swelling, but a return to his occupation produced recurrence. He had always been free from rheumatism. He came under observation nine months after the onset of the disease. Examination showed swelling of the muscles, extending downwards from the external condyle of the humerus about two and a half inches. The enlargement was confined to the muscles which arise from the condyle, and especially involved the supinator longus, the extensor carpi radialis longior, and brevior. The muscular bellies were firm and painful on deep pressure. The overlying skin was normal and there was no œdema. Sensation was perfect and no tender points could be found along the nerves. The electrical reactions were normal. There was neither spasm nor incoördination of movement when the patient followed his employment, it was only pain that compelled him to desist. The use of the arm in other occupations did not aggravate the condition. The patient illustrated the usual movements of wood-carving, which showed that the affected muscles were predominantly used, thus conclusively proving that the malady was an occupation disease.

INFECTION AND PARENTAL RESPONSIBILITY.

THE dangers connected with infectious disease have never been so clearly explained or so widely published as in our own day, consequently it is inevitable that the neglect of due precaution in respect of them should be legally punishable. In view of these facts two sentences in the Croydon county court imposing a light fine in each case upon defaulting parents cannot be considered even moderately severe. We mention them here because the offence committed is far from being uncommon, though it probably still escapes notice in a majority of instances. Sometimes it is, no doubt, a result of ignorance, but just as often, if not oftener, it is due to carelessness. How can we explain otherwise the frequency with which an infectious fever is caught at school? At the present date we commonly find that scarlet fever, or measles, if of a mild type, is treated as a mere common-place on the authority of some grandmotherly custom. No medical man is summoned, no sanitary precaution used, no notification, where this is called for, is made. In the case of whooping-cough, a disease of very grave import to young children, though not included in the schedule of the Act, this heedlessness is of daily occurrence. Such facts show clearly that, in spite of an increased knowledge of the power of contagion, many parents have still the most elementary sense of their responsibility with regard to it. It is therefore the more necessary that medical men and sanitary officers should do all that in them lies to instil a proper sense of the duty of precaution into the public mind. No alarmist attitude is required but is rather to be deprecated. The necessity, however, of isolation even in doubtful cases and at doubtful stages of disease, must be kept in view and instilled by precept and example.

THE treasurer of Guy's Hospital has received a donation of £1000 from the committee of the American Victoria Jubilee Fund to endow in perpetuity a "Queen Victoria Bed."

DR. R. R. RENTOUL, one of the recently elected Direct Representatives of the profession on the General Medical Council, has resigned his seat on that body.

DR. BYROM BRAMWELL has been elected an honorary member of the Société des Médecins Russes de St. Pétersbourg.

NOTE UPON THE TOXIC EFFECTS OF THE SWEAT OF A HEALTHY MAN.[1]

BY S. ARLOING.

II[2]

[WE published last week the first of two papers recently contributed by M. Arloing to the *Comptes Rendus* on the toxicity of normal human sweat, and to-day we give the second in the form of an unabridged translation. The following comment contributed by M. Berthollet on the earlier occasion upon which the subject was brought before the Academy of Sciences is of highly curious interest in this connexion. It will be seen from our correspondence columns that it has obtained currency in some of the continental journals in a slightly inaccurate form. M. Berthollet remembered having read the following in a work entitled "Mappæ Clavicula"—collection of ancient recipes (recipe 265): "Sudorem equi, quem in dextera parte inter coxas habuerit, sume, et intinge sagittam. Hoc expertum est utiliter." He suggests that it might be interesting to study the relation of this old prescription with M. Arloing's experiments.]

In a note inserted in the *Comptes Rendus* of July 26th last I briefly indicated the sum total of the characteristic features of poisoning by sweat, and gave in same details the evil effects produced on the circulation. I now propose to set out in the same manner the toxic symptoms produced on some other functions, still taking the dog as the type.

a. The mechanical phenomena of respiration are modified in number, amplitude, and form. I have already remarked in the preceding note upon the profound disturbance

[1] Translated from Comptes Rendus, vol. CXXV., No. 5, Aug. 2nd, 1897, p. 183.

[2] No. I. was published in THE LANCET of Sept. 4th, 1897.

Digitized by Google

occasioned to the respiration shortly after the introduction of the first dose of sweat into the blood. This disturbance, indicative of a violent excitement, is modified as a result of subsequent injections, and consists then in a considerable prolongation of the expiratory phase. Little by little, in proportion as the animal passes into a sort of hypnotic state, the respiratory movements diminish in number, become increasingly deep, and give rise to marked variations of arterial pressure. Furthermore, the inspiration is often accomplished by two well-defined efforts. Eventually the pneumographic curves are broken by slight irregularities occasioned by shiverings or tremblings, which shake the body of the subject at this stage. Finally may be noticed the modifications which precede and accompany the vomitings which are usual at this stage of the poisoning process. If, proceeding as I did in the study of the disturbances affecting the circulation, the respiratory movements are registered eight or ten hours after the last injection, during the stage of prostration, it is observed that the respiration has recovered its initial frequency, but is not so deep; that the inspiration is harsh and convulsive; that the thorax contracts rapidly at first, afterwards so gradually that it would be easy to believe that a long pause occurred during expiration. In one experiment, which may be regarded as an average case, there were 21 respirations a minute before the injections, 9 after the injections during the hypnotic stage, and 20 during the stage of prostration. In brief, the respiratory movements show, but rather by their form than by their number, that the nervous centres are affected by the sudoral poisons.

b. The mean temperature commonly falls in the course of the intravenous injections, but it is rapidly recovered, and after about four hours it rises above the normal by from one and a half to two degrees. It is not necessary for the production of a rise of temperature to administer a lethal dose; it may be observed in almost the same measure after the injection of a feeble or moderate dose. It coincides with general shivering attacks, lasts for about two hours, undergoes thereafter a sharp reduction of from a half to one degree, and oscillates for a considerable time about this *febrile* temperature. Then one of two things will occur; either the subject recovers, and in that case the temperature returns by degrees to the normal during the following days, *or* death may ensue, and in that case the temperature falls pretty quickly below the normal. It happens only very rarely that the subject dies, except there be a sub-normal *temperature*. When the dose is large or the sweat hypertoxic the temperature falls continuously after the injection without any further rise till death.

c. Over and above the effects upon the cardio-pulmonary nervous system I ought to mention the influence exerted by the injections upon the nausea-producing centre (*le centre nauséeux*) and upon the spinal marrow. It is impossible to deny that a relation of cause and effect may subsist between the sickness and the violent gastro-duodenal congestion occasioned by the sudoral poison; nevertheless, I can affirm that there is a direct action of this poison upon the nausea-producing centre, for I have observed vomiting to occur at the beginning of injections of concentrated extracts before the occurrence of any of the phenomena of congestion. The sweat secreted during and after muscular effort is more productive of vomiting than the secretion occasioned by artificial means after prolonged repose. The action upon the spinal marrow is manifested in many instances by excessive weakness of the hind limbs and of the lumbar region. There may be adduced, moreover, as evidence of an effect produced upon the nervous axis, the shiverings and tremblings which in the end involve almost all the muscles, shiverings and tremblings which are thrown into rhythmic action by the inspirations, and in some case choreiform movements of the limbs and spasmodic contractions of the diaphragm. Finally, as the sweat diffuses through the blood it produces an immediate exciting effect upon the muscular tissue of the intestine.

d. One of the most remarkable effects of poisoning by sweat is that produced upon the corpuscular constituents of the blood. *This rapidly diminishes from the first day and takes a long time for renewal in case the poisoning does not result in death. Thus in two dogs, four hours after the injections, although the febrile reaction was at its maximum, the number of red corpuscles* had diminished by about 1,000,000 *per cubic millimetre.* The following day the *temperature had returned to normal*, the number of red *corpuscles had diminished in the* one case from 5,940,000 to 3,732,000, and in the other from 5 100,000 to 3,280,000. A month later the subjects were still anæmic, although according to the report they were tending to return to the normal condition. The anæmic condition is accompanied by considerable emaciation; in three or four days the subjects lose more than one-third of their weight. If the malady lasts for a certain time sugar disappears from the blood and from the liver at the moment of death. At this moment also the urine is albuminous. The phenomena of nutrition and of the urinary secretion are therefore more or less profoundly affected by the presence of sweat in the blood. I have endeavoured to obtain evidence of this by an exact study of the excreta and of the chemical composition of the urine of animals submitted to a uniform course of feeding and one calculated to maintain a uniform condition of the organism. Immediately after the introduction of the poison the proportion of urea, of chlorides, and of phosphates in the urine is increased. Although the chlorides attain their maximum at the end of about four-and-twenty hours the urea and the phosphates do not attain theirs before forty-eight hours. Subsequently this proportion gradually falls. At the end of five days the phosphates continue to fall, but more gradually; the proportion of chlorides and of urea, on the contrary, tends to rise anew. But if account be taken of the quantity of urine secreted it will be found that the total amount of these substances eliminated during the five days following upon the injections is slightly below the normal. The greatest difference is presented by the chlorides, then by the urea, and least by the phosphates.

e. Now if we examine the symptoms of poisoning in the rabbit we shall find both analogies and differences. Of course, the vomitings do not occur, but the shiverings may be observed, the reduced temperature, the depression, the prostration, and sometimes the paresis of the hinder limbs. The first doses call forth violent contractions of the intestine, which produce movements of the walls of the abdomen in places. The pulse is much accelerated. The thoracic walls are agitated by rapid and jerky respirations. I have observed some constriction of the small vessels of the ear, but the pupil retains its mobility unimpaired. At last the animal falls into a lethargic condition, râles embarrass the respiration, the sensibility of the cornea diminishes, and a few convulsions precede death.

f. As for the guinea-pig, it becomes miserable, it shudders, its fur stands on end, it huddles itself together, its respiration becomes much accelerated, it utters faint cries from time to time, and finally it succumbs without exhibiting any more characteristic symptoms.

To sum up, if we take a survey of the symptoms described in this article and the preceding one we come to the conclusion that sweat contains some energetically poisonous substances, occasioning more or less derangement to all parts of the organism, disturbing the intimate phenomena of nutrition, modifying the composition of the blood, substances the properties of which possess a strong analogy to certain microbic toxins.

THE INCREASE OF DIPHTHERIA.

MR. D. T. BOSTEL'S letter (which we publish in another column) almost embraces the whole sanitary question—viz., (1) drain air as a means of propagating disease, (2) public sewers, (3) private drains, and (4) the duties of the local authorities. As the subject is at the moment one of very general interest a brief allusion to the points raised may be given.

First, with regard to insanitary surroundings causing or extending an epidemic of diphtheria. The specific infective poison of this disease differs from most others of an infectious nature in that the micro-organisms producing it are never found in the blood or in any of the internal organs. The bacilli in the human subject are only found in the mucous membrane of the throat.

It has been concluded that the action of the specific bacillus upon a weakened mucous membrane gives rise to a specific inflammatory process by the direct action of the poisonous products formed on the surrounding cells and blood-vessels, and produces the false membrane characteristic of the disease. These bacilli, though they may be present in the mouth, can exert little or no injurious effect

Digitized by Google

unless the mucous lining of the throat, larynx, &c., is already affected by some minor disease, but inflamed tonsils or ulcerations of the mucous membrane offer at once a favourable field for their operations.

There is a theory prevalent[1] that diphtheria is greatly influenced by damp, or rather by the level of the subsoil water, outbreaks of the disease so frequently occurring on the subsidence of water after a flood. This is, however, most likely due to the pollution of the sources of the drinking water by the flood from the surrounding cesspools, manure heaps, &c., by which means those who drink such water are prepared for the reception of the specific bacillus.

Dr. Klein believes cats to be a frequent source of transmission of infection. He is also of opinion that milk is another means of spreading the disease, though the question of its occasionally producing small pustules on the udder of the cow is still an open one. The wise will, however, see that their milk is boiled before use.

Dr. G. Sims Woodhead advises in any weak condition of the throat, not merely gargles, but application to the throat of antiseptic lotions, while plenty of fresh air and exercise should be taken combined with good food to promote the excretion of effete products, and that the cells may be able to play their part as phagocytes. He also states that the tenacity of life of these organisms at ordinary temperatures is very great—they retain their vitality for six months; and he advises that after a case has occurred the free use of boiling water is the best disinfectant, as a moist temperature of 136 4° F. will completely destroy them in a few minutes.

The very general distribution of the virus of diphtheria in an attenuated form makes it highly important that any unfavourable surroundings that tend to depress the vital powers, such as the emanations from a foul drain, which are especially liable to affect the throat, should be promptly corrected, otherwise a condition is established most favourable to the development of such bacteria, which then rapidly regain their virulence.

Secondly, the defective condition of many public sewers is much to be deplored. It is to be feared that there are few parishes in London in which some old and defective sewers do not exist. In some the brick bottoms have decayed and sunk, permitting large accumulations of deposit. Gases are generated in these to such an extent that the men who have occasion to wade through them dare not do so with a light for fear that their movements would free the gas in such volumes as might cause a fatal explosion.

The third point, relating to private drains. Houses in the neighbourhood of such sewers are liable to be affected by the emanations from them; these may travel along the course, not only of the house drains, but of the gas and water mains leading from the road.

Lastly, as to local authorities. The vestryman, with a view to future election, is often more desirous of spending public money upon improvements that command general attention than upon a buried sewer. The motto, "Let sleeping dogs lie," is one that frequently finds acceptance in connexion with drains and sewers.

The question on drain testing opens up rather a wide subject, but there can be no doubt that a drain that will hold water with a head of two or three feet must be a perfectly sound one. How long it will continue to be so if constructed of stoneware pipes is another matter.

SOME LITERATURE CONCERNING THE PLAGUE.

(Concluded from p. 559.)

THE report of the Commission sent by the Egyptian Government to Bombay to study plague is an excellent and interesting official document. In view of the rapid extension of plague in Bombay, and the possibility of infection of the Mecca pilgrimage by Indian pilgrims, the question very naturally arose of the danger of infection of Egypt, and it was consequently thought desirable that the sanitary authorities of that country should have the opportunity of studying the disease on the spot, as there had been no occurrence of epidemic plague in Egypt since 1845. A mission composed of the Director-General of the Sanitary Department (Dr. Rogers Pasha), the Director of the Hygienic Institute at Cairo (Dr. Bitter), and the Director of the Medical School, Cairo (Dr. Ibrahim Pasha Hassan), with a complete equipment for fitting out a bacteriological laboratory, accordingly started, and arrived in Bombay on Jan. 24th last. The report deals with the epidemiology and medical history, and with the clinical, pathological, and bacteriological aspects of the disease. It did not come within the scope of the mission to enter upon any criticism as to the measures adopted in Bombay for the control of the disease, or to express any opinion as to the practicability of applying measures to that end in a city like Bombay, where so many complex questions of race, caste, and religion arise. The mission found on arrival, a general infection of the city and an extension into the neighbouring country. There was no really efficient system of death-registration in Bombay, and if the official statistics of deaths attributable to plague be taken there was also a co-existing epidemic mortality from other diseases, as was pointed out at the time, and as is clearly shown by comparing the death-rate of the plague year with that of ordinary years, notwithstanding the large exodus which, owing to the fear of plague, took place from Bombay. We gather from the report that the conclusions arrived at were:—that the plague spread through human beings, and that the part played by rats, flies, &c., in the propagation of the disease was probably a very small one, and that, in the first instance, it was the individual, and not the locality, which was infected. It follows, of course, that the prompt isolation of the sick and infected and the evacuation of houses and rooms and their efficient disinfection are essential preventive measures. We need scarcely add that for any disease-cause to take root and flourish there must, as in the case of any seed, be a suitable state of soil and environing conditions, and unhappily these exist in abundance in most oriental cities and places, but the removal of them is difficult, and in any case means the outlay of money and time, as well as, commonly, interference with ignorant prejudices, social and religious customs, and habits. It is easy to understand that, owing to political considerations and questions of expediency, governments are very reluctant to take the necessary steps at the right moment in a matter when time, unfortunately, forms an essential element of success. The usual course is for the local government to neglect the advice of their duly constituted official advisers or to postpone giving effect to it until the mischief is done and the pressure of public opinion begins to be felt, and even then, as in the case of Bombay, extraneous advice is sought for in support of the necessary measures before action is taken. As Dr. Rogers points out, the progress of plague in the Bombay Presidency was relatively slow as compared with that of epidemic cholera, for example, and thus allows of much more time for the application of sanitary and precautionary measures for stamping out the disease, if only the cases can be detected, and for that an effective system of death-registration is obviously necessary. In this connexion we may call attention to the government resolution and papers published in the *Government Gazette* for the North-Western Provinces and Oudh relating to the outbreak of bubonic plague at Hardwár in April, May, and June last, and the measures adopted for its suppression. The outbreak presented some peculiar features, and was a very striking and interesting illustration of what can be accomplished by logical methods of sanitary procedures when wisely and judiciously carried out. The facts detailed in the official correspondence making up the medical and sanitary history of the occurrence are too long for us to set forth, but the sanitary commissioner, Surgeon-Major S. J. Thompson, D.P.H Camb., and all concerned showed considerable administrative ability and skill in the arrangements they made as did the executive and sanitary officers in carrying them out. They certainly merit the highly appreciative terms in which their services are spoken of in the government resolution. The general result was that the outbreak in the great centre of Hindu pilgrimage was fully met and the disease stamped out without prohibiting the holding of the various fairs and bathing festivals. No case of plague occurred among the myriads of pilgrims who visited Hardwár. Returning, however, from this digression to the subject of the report of the Egyptian Sanitary Commission we may say that the system of preventive inoculations is made the subject of critical comment and remarks. That immunisation of the

[1] See THE LANCET, August 28th, 1897, p. 563.

Digitized by Google

individual against plague may be arrived at is not only possible but probable; still, their efficacy in this respect has not yet been established. We do not ourselves see why practical sanitary measures should not go on while this method is being tried, but if it should be the case, as suggested, that recourse to such inoculations is likely to lead to the neglect of sanitary precautions of proved efficacy, then there is much force in what is urged in the report under review. It seems to us that the objections which might be urged against the practice are that the efficacy of such preventive inoculations has not yet been demonstrated; that they are painful, and attended with some fever; and that we do not know how long the alleged immunity lasts, and it appears impracticable to carry them out on so extensive a scale as is required for the protection of a population. In our present state of knowledge the recognised methods of dealing with epidemic diseases are the safest and best—viz., to search out and isolate the sick and segregate the infected as soon as possible, and to do all in our power in the intervals of their appearance to remove obvious causes likely to prejudicially affect the public health—by providing pure water supplies, good air, and cleanliness of soil. "Plague," says Dr. Rogers, "is not, in my opinion, and Dr. Bitter shares my views, a disease likely to take very firm hold amongst pilgrims living under canvas and constantly on the move." He considers, too, that there should be no unreasoning panic as to the danger of propagation of plague by commerce. After briefly describing the general state of things and the means available in Egypt for combating epidemic disease the Director-General of the Sanitary Department says that, on the whole, he considers himself justified in stating that the danger to Egypt from plague should not be very great. We have so extended our remarks on this practical and able section of the report that little or no room has been left for the remaining sections, dealing with the more scientific and medical and clinical aspects of the disease by Dr. Bitter and others. It must suffice to say with regard to these that they seem to us to have been very carefully and well done and will well repay perusal and consideration. "The Experiences and Lessons of the Bombay Plague," by Thomas Blaney, is a reprint of some able papers that appeared in the *Times of India*, in which the life of the plague epidemic in the population is traced in an interesting and suggestive way through its three successive stages—viz., its invading or spreading stage, its maximum degree of epidemic extension, and its third or declining stage, with reference to the measures which are applicable to them. The subject is well worked out and lucidly set forth, with a practical aim in view.

SMALL-POX AND VACCINATION IN ZULULAND.

A CORRESPONDENT writes: "As the subject of vaccination is one of never-ending interest the following case may be instructive as well as interesting.

"In November of last year a supposed outbreak of small-pox was reported to me, as one of the district surgeons in Zululand, as having broken out in my district, and on going to investigate I found six cases of a mild type in a convalescent stage. The infection I traced to a native recently returned from Johannesburg. There were four Kaffir kraals, of several huts in each, on the top of a hill, in such a situation as to render them most easy of isolation. I at once vaccinated and re-vaccinated all unprotected inmates, and placed a police guard round the hill, cutting off all communication with the outer world. Owing to part of my lymph being rather old several cases missed and had to be done over again, unfortunately not in time to prevent them contracting the disease; all of them did take it, one, an aged woman, very severely, almost in the confluent form. Her only garment was a short petticoat reaching to her knees. She had the sole charge of an infant, about eighteen months old, whose mother was away. This infant would not leave her night or day, slept with her, and was carried about by her, either on her back, or under her arm, the child being quite naked, rubbing off the tops of the pustules and well rubbing the virus into its own skin. The child had been vaccinated in four places and had taken well. I do not suppose either woman or child was once washed during the whole period of illness, and yet the child escaped small-pox infection. Could there be any better test of the efficacy of vaccination? Also, there were no cases of small-pox among those successfully vaccinated, though they mixed freely with the infected, even sleeping in the same huts. After an interval of twenty-one days from the termination of the last case I supplied each inmate with a piece of carbolic soap and sent them to the nearest spruit (brook) to wash themselves, making them leave their clothing, which was inconsequential, behind; I had it all hung up in the huts during their absence, the entrances being closed and the huts fumigated with sulphur. I would have much preferred to burn both huts and clothing, but was not allowed to do so; however, there was no return of the disease."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bristol Urban District.—The population of Bristol was estimated during 1896 at 230,623, but if the proposals for the extension of the borough are carried into effect Bristol will be very considerably increased both in population and in area. In connexion with the subject of water analysis Dr. D. S. Davies reports that twenty-one samples of water from local wells were examined by the city analyst, and with one exception all were found to be polluted. The exception afforded an interesting example of the futility of relying on analysis alone, whether be it chemical or bacteriological. The difference in the analysis during periods of drought and during those of heavy rain was most marked, and afforded a good example of the necessity for gauging risks rather by the surroundings of a well than by the analysis of its waters. Dr. Davies refers in his report to the complaints of the smells arising from the River Avon, but there is really nothing to add to the remarks we recently made on the subject in our columns; in fact, those remarks were in large part founded upon a notice of the report now before us. The subject of public slaughter-houses has been under the consideration of the sanitary committee during the year, and Dr. Davies, in a special report, states that the abattoirs of Bradford pay 6 per cent., of Manchester 4 per cent., and of Birkenhead 5 per cent.; and it seems probable that Bristol will soon be provided with these excellent preventatives of the sale of unwholesome meat, and, we may add, of unnecessary cruelty. The corrected death-rate of Bristol during 1896 was 17·59 per 1000, and the infantile mortality 135·9 per 1000 births. Concerning vaccination Dr. Davies reports that during 1895, the latest available returns, 73·06 of the children born were vaccinated. We wonder in all these cases how many insertions of lymph were made. In considering the bacteriological examination of diphtheria Dr. Davies states that in 1896 the test proved unreliable in 12 per cent. of the cases examined, and he points out that this failure may be due to errors in manipulation, in observation, or through the media being improperly prepared. Of errors in manipulation an instance is given where the wrong side of the cotton swab was applied to the surface of the agar. As Dr. Davies points out, a single negative result must be accepted with extreme caution. Thirty-six cases of small-pox occurred in Bristol during 1896, several of them being traced directly to Gloucester. In reference to the epidemic of small-pox at this latter place Dr. Davies observes that in an epidemic of equal severity in Bristol—assuming that the state of vaccination was similar to that which obtained in Gloucester—there would have been some 2196 deaths of small-pox in the city of Bristol during less than seven months.

St. Olave's District.—Dr. W. A. Bond states in his annual report for this district that he received information of the treatment of 14 cases of anthrax at Guy's Hospital; all the cases were operated upon and recovered. Of the 14 patients 6 worked at wharves in St. Olave's, 6 in the tanyard at Bermondsey, and the remaining two had a relative who worked in the same tanyard. In all instances the patients who had become infected at the wharves had been manipulating goat skins from China within a few days of their

Digitized by Google

attacks. Dr. Bond is glad to be able to report that as regards means of prevention there is a decided tendency in the leather trade to adopt the "wet" instead of the "dry" cure, and that the "wet" cured hides are now considered superior to those "dry" cured. As Dr. Bond observes, great care should be taken at the centres of exportation to see that the hides of animals dead from anthrax are not mixed with those of healthy animals.

The City of London Sanitary District.—The figures yielded by the quinquennial census of 1896 furnish some interesting comparisons as regards the City of London with those of the 1891 census, which we noticed fully in our review of the annual report of Dr. Sedgwick Saunders, in which they were dealt with. The 1896 census showed that on the night of March 29th, 1896, the population of the City was 31,711, as against a night population of 38,320 in 1891, or, in other words, there has been in the five years which have elapsed between the two census returns a decrease of 6609. The estimated population for 1896 was 32,843, and the difference between the estimated and the actual population shows, Dr. Saunders observes, the desirability of more frequent enumerations of the people. The general death-rate of the City during 1896 was 17·8 per 1000, as against a rate of 18·3 for 1895, but it has to be noted that in these rates no allowance has been made for age and sex distribution. There were 915 tons of unsound meat seized in the City markets during 1896, the largest quantities being seized in the months from June to September. In his report as public analyst Dr. Saunders gives the result of certain analyses he made of foreign dairy produce, and they are interesting as having a distinct bearing upon the purity of our imported food supply. Samples of New Zealand butter were examined and found to be quite genuine, as also were those of Swedish, Australian, and Danish origin. Dr. Saunders points out that he made these analyses at the wish of the sanitary committee, but that this work forms no part of his duty as public analyst for the City. He considers that the Somerset House authorities might with profit undertake the examination of foreign produce.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS

IN thirty-three of the largest English towns 6071 births and 4362 deaths were registered during the week ending Sept. 4th. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 29·5 to 24·6 per 1000 further fell last week to 20·7. In London the rate was 17·0 per 1000, while it averaged 23·2 in the thirty-two provincial towns. The lowest death-rates in these towns were 10·4 in Swansea, 15·0 in Plymouth, 15·5 in Bristol, and 15·9 in Cardiff and in Huddersfield; the highest rates were 30·8 in Salford, 33·5 in Wolverhampton, 37·5 in Hull, and 44·4 in Preston. The 4362 deaths in these towns included 1272 which were referred to the principal zymotic diseases, against 2319 and 1783 in the two preceding weeks; of these, 1001 resulted from diarrhœa, 83 from measles, 62 from whooping-cough, 57 from diphtheria, 38 from "fever" (principally enteric), and 31 from scarlet fever. The lowest death-rates from these diseases were recorded in Swansea, Bristol, Plymouth, and Cardiff; and the highest rates in Salford, Wolverhampton, Hull, and Preston. The greatest mortality from measles occurred in Birmingham, Manchester, Oldham, Blackburn, and Preston; from scarlet fever in Salford; from whooping-cough in Plymouth and Wolverhampton; from "fever" in Sunderland and Burnley; and from diarrhœa in Blackburn, Leicester, Salford, Wolverhampton, Preston, and Hull. The 57 deaths from diphtheria included 35 in London, 5 in Liverpool, and 4 in Birmingham. No fatal case of small-pox was registered last week in any of the thirty-three large towns; and no cases of this disease were under treatment during last week in any of the Metropolitan Asylum Hospitals. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3528, against 3341, 3400, and 3448 on the three preceding Saturdays; 371 new cases were admitted during the week, against 347, 340, and 356 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 119 and 102 in the two preceding weeks, rose again last week to 116, but were 33 below the corrected average. The causes of 39, or 0·9 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Cardiff, Leicester, Nottingham, and in fourteen smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Salford, and Bradford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight principal Scotch towns, which had been 21·6 and 19·6 per 1000 in the two preceding weeks, further declined to 18·1 during the week ending Sept. 4th, and was 2·6 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 6·8 in Perth and 15·1 in Edinburgh to 23·5 in Leith and 23·6 in Dundee. The 538 deaths in these towns included 84 which were referred to diarrhœa, 19 to whooping-cough, 10 to scarlet fever, 5 to measles, 4 to diphtheria, 4 to "fever" (principally enteric), and 1 to small-pox; in all, 127 deaths resulted from these principal zymotic diseases, against 187 and 137 in the two preceding weeks. These 127 deaths were equal to an annual rate of 4·3 per 1000, which was 1·7 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 147 and 96 in the two preceding weeks, further declined last week to 84, and included 38 in Glasgow, 12 in Edinburgh, and 9 in Dundee. The deaths referred to whooping-cough, which had been 21 and 23 in the two preceding weeks, declined again to 19 last week, of which 13 occurred in Glasgow and 4 in Dundee. The 10 fatal cases of scarlet fever showed a further increase upon the numbers recorded in recent weeks, and included 4 in Edinburgh and 3 in Dundee. The deaths from diphtheria, which had been 4 and 1 in the two preceding weeks, rose again to 4 last week, of which 2 occurred in Paisley. The 4 fatal cases of "fever" corresponded with the number recorded in the preceding week, and included 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 62 and 78 in the two preceding weeks, declined to 69 last week, but were 11 above the number in the corresponding period of last year. The causes of 38, or more than 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·3 and 23·0 per 1000 in the two preceding weeks, rose again to 23·1 during the week ending Sept. 4th. During the past nine weeks of the current quarter the death-rate in the city has averaged 23·5 per 1000, the rate during the same period being 20·9 in London and 18·0 in Edinburgh. The 155 deaths registered in Dublin during the week under notice showed a slight increase upon the number in the preceding week, and included 33 which were referred to the principal zymotic diseases, against 39 in each of the two preceding weeks; of these 25 resulted from diarrhœa, 4 from diphtheria, 3 from whooping-cough, 1 from scarlet fever, but not one from small-pox, measles, or "fever." These 33 deaths were equal to an annual rate of 4·9 per 1000, the zymotic death-rate during the same period being 3·2 in London and 3·2 in Edinburgh. The fatal cases of diarrhœa, which had been 31 and 32 in the two preceding weeks, declined to 25 last week. The 4 deaths referred to diphtheria exceeded the number recorded in any week since the end of June, and the 3 fatal cases of whooping-cough also exceeded those registered in any recent week. The mortality from scarlet fever showed a further decline from that recorded in the two preceding weeks. The 155 deaths in Dublin last week included 46 of infants under one year of age and 33 of persons aged upwards of sixty years; the deaths of infants and of elderly persons exceeded those recorded in the preceding week. Eight inquest cases and 6 deaths from violence were registered; and 43, or more than a fourth, of the deaths occurred in public institutions. The causes of 13, or more than 8 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING AUGUST, 1897.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during August in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 10·2 per 1000 of the population, estimated at 4,463,169 persons in the middle of this year. In the three preceding months the rates had been 8·1, 8·7, and 11·2 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Paddington, St. George Hanover-square, Hampstead, Stoke Newington, Lewisham, Lee, and Plumstead; while they showed the largest excess in St. James Westminster, Holborn, Clerkenwell, St. Luke, Bethnal Green, Limehouse, and Battersea. Only one case of small-pox was notified in London during August, against 10, 4, and 7 in the three preceding months; this case belonged to St. Pancras sanitary area. No small-pox patient was admitted into any of the Metropolitan Asylum Hospitals during August, and none remained under treatment at the end of the month. The prevalence of scarlet fever in London showed a decline from that recorded in the preceding month; this disease was proportionally most prevalent in St. James Westminster, St. Luke, Bethnal Green, Whitechapel, Limehouse, Mile End Old Town, and Battersea sanitary areas. The Metropolitan Asylum Hospitals contained 3390 scarlet fever patients at the end of August, against 2495, 2786, and 3064 at the end of the three preceding months; the weekly admissions averaged 346, against 258, 272, and 364 in the three preceding months. The prevalence of diphtheria in London showed a marked decline from that recorded in the preceding month; among the various sanitary areas this disease showed the highest proportional prevalence in Holborn, Clerkenwell, St. Luke, Bethnal Green, St. Saviour Southwark, and Battersea. There were 1006 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of August, against 783, 864, and 957 at the end of the three preceding months; the weekly admissions averaged 131, against 108, 125, and 139 in the three preceding months. The prevalence of enteric fever in London during the month under notice showed a marked further increase upon that recorded in recent months; this disease was proportionally most prevalent in St. Pancras, Hackney, St. Giles, Clerkenwell, Shoreditch, Limehouse, and St. Olave Southwark sanitary areas. Erysipelas showed the highest proportional prevalence in Fulham, Clerkenwell, Shoreditch, Bethnal Green, St. George-in-the-East, and Rotherhithe sanitary areas. The 20 cases of puerperal fever notified in London during August included 3 in St. Pancras, 3 in Battersea, and 2 each in Paddington, Hammersmith, Bethnal Green, and Whitechapel sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, August 28th, the deaths of 8124 persons belonging to London were registered, equal to an annual rate of 23·7 per 1000, against 14·9, 13 9, and 18 3 in the three preceding months. The lowest death-rates during August in the various sanitary areas were 12 0 in St. George Hanover-square, 12·5 in Hampstead, 14·4 in St. Martin-in-the-Fields, 16·9 in Kensington, 17 3 in St. James Westminster, and 18·9 in Lee; the highest rates were 28·4 in Poplar, 28·8 in Shoreditch, 29 9 in Holborn, 30·2 in St. George-in-the-East, 31·3 in St. Luke, 32 2 in St. George Southwark, and 35·2 in Limehouse. During the four weeks of August 2532 deaths were referred to the principal zymotic diseases in London; of these, 2079 resulted from diarrhœa, 137 from diphtheria, 109 from whooping-cough, 108 from measles, 61 from scarlet fever, 37 from enteric fever, and 1 from small-pox. These 2532 deaths were equal to an annual rate of 7·4 per 1000, of which no less than 6·1 was due to summer diarrhœa. The lowest zymotic death-rates were recorded in St. George Hanover-square, St. James Westminster, Hampstead, St. Martin-in-the-Fields, and St. Giles; and the highest rates in Holborn, Shoreditch, St. Saviour Southwark, St. George Southwark, Newington, Bermondsey, and Rotherhithe sanitary areas. The single fatal case of small-pox belonged to Islington sanitary area. The 108 deaths referred to measles were 72 below the corrected average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Clerkenwell, St. Luke, Whitechapel, St. Saviour Southwark, St. George Southwark, and Camberwell sanitary areas. The 61 fatal cases of scarlet fever were 28 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Westminster, Shoreditch, and Woolwich. The 137 deaths from diphtheria were 21 below the corrected average number; the mortality from this disease was highest in Paddington, Marylebone, Holborn, Whitechapel, Newington, and Battersea sanitary areas. The 109 fatal cases of whooping-cough were 30 below the corrected average number; this disease was proportionally most fatal in Marylebone, Stoke Newington, Holborn, and Bermondsey sanitary areas. The 37 deaths referred to enteric fever were 8 below the corrected average number; the mortality from this disease showed no marked excess in any of the sanitary areas. The 2079 fatal cases of diarrhœa were considerably more than double the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Fulham, Holborn, Shoreditch, St. Saviour Southwark, St. George Southwark, Bermondsey, Rotherhithe, Woolwich, and Plumstead. In conclusion, it may be noted that the mortality in London during August from these principal zymotic diseases was nearly double the corrected average, owing to the excessive fatality of summer diarrhœa.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 366 per 1000, and considerably exceeded the average, owing principally to the excessive fatality of diarrhœal diseases. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, St. James Westminster, Marylebone, St. Luke, City of London, and Mile End Old Town; and the highest rates in Holborn, Limehouse, St. George Southwark, Rotherhithe, Greenwich, and Woolwich.
